". . . . chronic enlargement of lymph glands . . . . may often be due to persistence of infection as a result of a Vitamin A deficient diet."

The above conclusion was drawn from the results of an investigation *(Lancet.* May 23rd. 1931, 1151) in which it was found that a deficiency of Vitamin A leads to a rapid deterioration of the lining of the *"respiratory passages, the urinary tract, the reproductive tract, the conjunctiva, the nasal passages, the ear, and the ducts of organs"*—making *"breaches in the walls of the body's defences, through which the invading microbe may enter."*

Radiostoleum provides the means of supplying measured quantities of Vitamin A, which will *"maintain the functional integrity of the walls covering body-surfaces, thereby preventing invasion of the organism by microbic agents."* Further, there is additional advantage accruing from the collateral action of its standardised content of Vitamin D also.

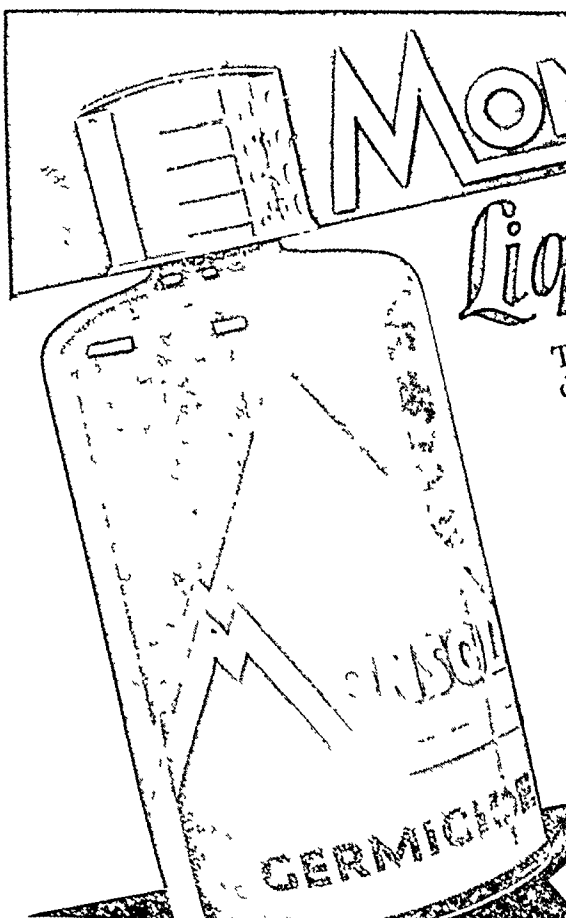
ALKA-ZANE

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions

is a palatable and rational antacid, indicated in all conditions of relative hyperacidity, rheumatism, gout, intestinal, gastric, and certain cutaneous disorders.

Prompt in action, lasting in effect, it promotes diuresis, neutralizes excess acid production and helps to rebuild the alkaline bases.



The efficiency of Alka-Zane is demonstrable by the briefest of trials.

A supply for clinical use and literature sent gratis to physicians on request.

MONSOL
Liquid GERMICIDE

The use of MONSOL in Obstetric Practice is daily gaining ground and replacing the caustic disinfectants used in the past. The reason being that Monsol has a Selective Action on the Streptococcus Pyogenes, notably the Strain Haemolyticus, and being NON-CAUSTIC can be used at adequate strength to kill these bacteria without the slightest harm to the most delicate tissues. Literature and a clinical sample, together with special price list, will be sent to members of the Medical Profession on request.

These essences prepare the patient to accept a solid diet

When the system is in an exhausted condition Brand's Essences of Beef or Chicken stimulate, supply energy and prepare the patient to accept a solid diet.

Even in cases of very advanced stomach atonicity the essences make possible an amazingly quick return to normal tone and acidity.

99 out of every 100 doctors recently interviewed depend on Brand's Essences of Beef or Chicken in the treatment of specific fevers, in disorders associated with pyrexia, before and after operations, in cases of intestinal disturbances, in the post-influenzal state, and in convalescence when the patient's recovery is hampered by anorexia.

The finest freshly killed English meats are used in the preparation of Brand's Essences of Beef or Chicken. By an exclusive process the pure essence is expressed and hygienically conserved without preservatives, easy to swallow and delicious to taste.

On the receipt of a professional card samples will be gladly sent.

Write to Brand & Company, Ltd., Dept. F39, Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S ESSENCES OF BEEF OR CHICKEN

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Compound Syrup of Hypophosphites "Fellows" contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

Compound Syrup of Hypophosphites

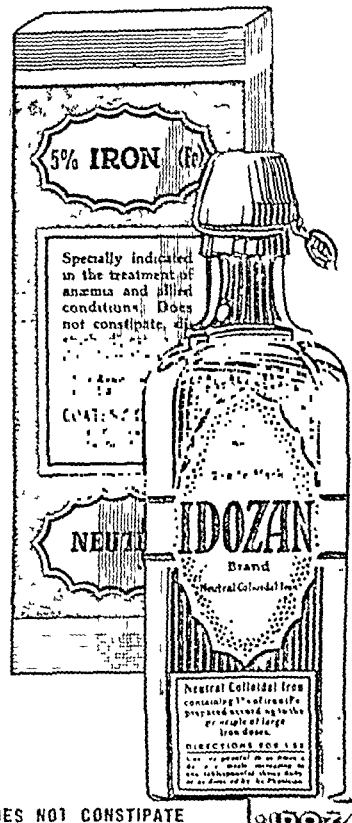
A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.



Alasil" completely overcomes this objection By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract "Alasil" is therefore a triumph over acetyl-salicylic acid It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time Analgesic, Antipyretic, and Sedative "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

Alasil

M 275

Effective Ferrotherapy

IDOZAN IS A COLLOIDAL IRON SOLUTION, NEUTRAL, AND CONTAINING 5 PER CENT. OF PURE IRON (Fe).

One teaspoonful of IDOZAN contains 25 ctgrms. of pure iron (Fe).
One dessertspoonful of IDOZAN contains 50 ctgrms. of pure iron (Fe).
One tablespoonful of IDOZAN contains 75 ctgrms. of pure iron (Fe).

Thus, by means of relatively small doses of IDOZAN it is possible—without any inconvenience to the patient—to give much larger doses of iron than could be accomplished with many of the older preparations. In cases of severe anæmia, for instance, one may very well give the patient one tablespoonful of IDOZAN three times daily. This dosage means a daily intake of 2.25 grams of pure iron.

Packings—8-oz. & 40-oz. bottles.

DOES NOT CONSTIPATE
DOES NOT DISCOLOUR THE TEETH
DOES NOT PRODUCE STOMACH DISCOMFORTS

"IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES"

IDOZAN

Cod-Liver Oil Cream

This ethical preparation is particularly acceptable to children. It may be prescribed with confidence that good results will be obtained.

Children take it readily, even where the usual difficulty has been experienced in inducing them to take other forms of Cod-Liver Oil. They rapidly respond to its nutritive and strengthening influence.

The Cream contains 50% of recently refined Cod-Liver Oil of high vitamin content. The fresh eggs used in the making enhance the value of the preparation as a nutrient. The Emulsion is perfect (vide *The Lancet*, Jan. 4th, 1930), rendering the assimilation easy, even in cases where digestion is weak.

The fact that it is freshly prepared every week ensures freedom from loss of vitamin efficiency of the oil, due to storage or exposure to sunlight.

The preparation is endorsed by many members of the Medical Profession

Alimentary Toxæmia and Neurasthenia

Intestinal Disinfection

NEURASTHENIA is no doubt a comprehensive term which includes several affections of different ætiology

In many of the cases alimentary toxæmia plays a considerable part, the digestion is upset and flatulence is frequent, the bowels are fickle in their action, and the indican and ethereal sulphates in the urine are markedly increased—sure signs of putrefactive changes in the bowel

In this class of cases intestinal disinfection is one of the principal lines of treatment to be adopted, and for this purpose nothing surpasses the use of Kerol Capsules

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol One to three capsules may be given three or four times a day after meals.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men

"After using 'Staniform' Ointment in cases of Impetigo and other scaly conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform Ointment'"

"Festering wound on left heel—when first seen was about the size of a shilling with a good deal of pus Foot much swollen—dressed with 'Staniform' Ointment—healed splendidly in four days"

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties Combining the well known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing

BABY'S ONLY FOOD FROM BIRTH TO 2½ YEARS

ROSARIO
18th May, 1931

To Messrs. Cow & Gate, Ltd.
Guildford, ENGLAND

Dear Sirs,

Until two months ago Baby has been existing only on Cow & Gate milk, as she refused to take any solid food. Everyone told me she ought to be eating other food, but evidently what she did have made up for it, and everyone remarked how bonny she was and what strong bones and muscles she had. We would not be without it for worlds and thoroughly recommend it to all our friends.

She still has three breakfast-cups a day—one on getting up in the morning, one at siesta time and one on going to bed—and thoroughly enjoys it and has never had one minute's discomfort, even during our extremely hot summer days. She is very intelligent and bright.

I remain, Yours very truly Hilda J. Taylor.

LIVER THERAPY

HEPATEX

This is a palatable extract of liver concentrated so that a teaspoonful dose contains the therapeutic principles of 2 ozs. fresh liver, including the full Vitamin B complex. It is well recognised to be the most convenient form of liver preparation for administration by the mouth, and is highly effective, not only in pernicious anaemia, but also in the severe secondary anaemias.

Being a rich source of Vitamin B_1 and B_2 it may be used to advantage in many anaemic and debilitated conditions where a general tonic is indicated.

Issued in 4-oz. bottles.

HEPATEX P.A.F.

This new preparation, recently introduced by us, is a solution of the liver fraction suitable for intramuscular or intravenous injection in those cases of pernicious anaemia where an immediate response is essential. It has already created an unusual amount of interest because of its consistent success in the variety of cases in which it has been tried. It is not only of great value where speed of action is desired, but also in those cases where liver extract taken by the mouth is contra-indicated for some reason or other.

Issued in Ampoules 5 c.c.

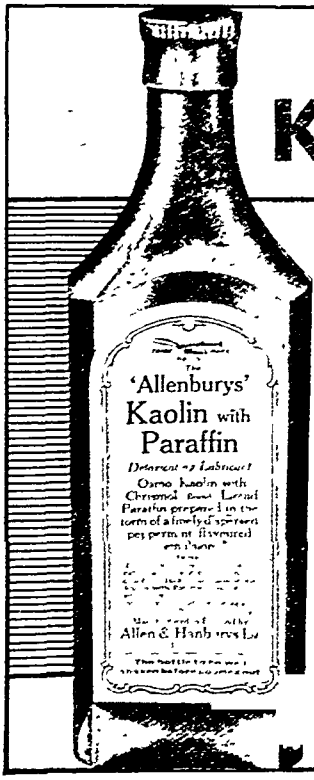
"I-so-gel" Granules

Indicated in Chronic Constipation, Colitis, and allied intestinal disorders

"I-so-gel" is a natural vegetable material. The granules absorb many times their volume of water and swell into a gelatinous mass which both stimulates natural intestinal movements and soothes inflamed intestinal mucous membrane. Indicated in chronic constipation, colitis, and allied intestinal disorders. Action purely mechanical. Sugar-free. Ideal for diabetics.



In bottles at 2/6 and 4/6 each

Descriptive literature sent post free on application.

Allen & Hanburys Ltd., London, E.2

Telephone: 3201 Bishopsgate (10 lines). Telegrams: "Greenburys Beth London."

The 'Allenburys' Kaolin with Paraffin

A Detoxicating Lubricant

The "Allenburys" Kaolin with Paraffin contains a combination of two already well known preparations —20 per cent. of "Osmo" Kaolin with 33⅓ per cent. of "Chrismol" Liquid Paraffin. These two constituents are so finely diffused that they form an emulsion which ensures the highest possible therapeutic effects.

The "Allenburys" Kaolin with Paraffin is indicated in all conditions in which elimination of intestinal toxins and protection of the intestinal mucosa are necessary, *e.g.* in chronic constipation, intestinal toxæmia, colitis, summer diarrhœa, food poisoning, cholera, etc.

In bottles: 8 oz. and 16 oz. for prescribing
80 oz. for dispensing

Literature and clinical trial samples will be sent post free on application.

A PIONEER ENGLISH NATIONAL COUNCIL—THE WITAN OR WITANAGEMOT.—Ethelbert (A.D. 616) established, with the help of his council of wise men, judicial decisions after the Norman model—which are written in the language of the English, and are still kept and observed by them. This is the first recorded instance of legislative action by the Witan. In A.D. 672, King Edwin of Northumbria, "holding a council with the wise men, asked of every one in particular what he thought of this doctrine (*i.e.*, of the Christian religion) hitherto unknown to them, and the new worship that was preached." In about A.D. 685 the great Caedwalla introduced written law into Wessex, and the famous "Dooms of Caedwalla" were drawn up by the King and his Witan. (The decisions of this assembly were called "dooms.") In the same way were enacted the "Dooms of Ine," his successor, whose code still exists. All the English kingdoms seem to have possessed this assembly, the *witanagemot* or "meeting of the wise"; the number of Witans varied with the number of kingdoms, until, in the ninth century, there were one King and one Witan. The name disappears about the time of the Norman Conquest. The illustration is from an Anglo-Saxon manuscript.

A NEW PREPARATION FROM THE GLAXO LABORATORIES

GLUCOSE-D

GLUCOSE-D is a medicinal glucose (98%) of the highest quality, and of a pleasant form for administration, combined with Ostelin Vitamin D and an easily assimilable calcium-phosphorus compound.

The Treatment of Acidosis

Acidosis has come to be recognised as a relatively common disorder, particularly in childhood. Treatment by a low fat diet and the administration of glucose is a settled principle of therapeutics. A low fat diet removes the source of vitamin D from the diet. Moreover, foods deficient in fat are frequently deficient in calcium also. Glucose-D is, therefore, the preparation of choice in cases of acidosis. It can also be administered in all cases, such as heart disease, where glucose is indicated.

GLUCOSE-D IS SOLD IN 1-lb. TINS AT 1/9.

A supply for clinical trial will be forwarded immediately to any doctor writing to:
GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1.

Wherever calcium is prescribed . . .

Wherever calcium is prescribed for adult or child, order Ostelin Vitamin D as well, to ensure efficient utilisation.

OSTELIN VITAMIN D
("Ostelin")

In liquid form. Is compatible with other medicaments.

For incorporation in aqueous mixtures: in bottles of 2, 4, 8 and 16 oz. at 5/- per oz.

Also OSTELIN TABLETS
OSTOMALT OSTELIN EMULSION

ADEXOLIN CAPSULES

Vitamins A and D highly concentrated

For general use in infective processes. To prevent and abort colds and other diseases of the respiratory tract. As a prophylactic during the later months of pregnancy.

In boxes of	per box
25 capsules	3 9
100 capsules	12 6

ERBOLIN CAPSULES

Ergot in ideal form

Standardised ergot, in defatted powder form, which tests have shown to retain full potency for over two years.

In bottles of	per bottle
25 capsules	3 4
100 capsules	10-

Also supplied in bottles of 500 and 1000 capsules

Usual professional discount

GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1.

ON
A CASE OF INTRACRANIAL TUMOUR

BY

A. F. TREDGOLD, M.D., F.R.C.P., F.R.S.ED.

ASSOCIATE PHYSICIAN IN PSYCHOLOGICAL MEDICINE, UNIVERSITY COLLEGE HOSPITAL, LONDON; PHYSICIAN IN NEUROLOGY, ROYAL SURREY COUNTY HOSPITAL

WITH A PATHOLOGICAL ACCOUNT

BY

E. T. RUSTON, M.B., CH.B.

ASSISTANT PATHOLOGIST, ROYAL SURREY COUNTY HOSPITAL

(With Special Plate)

It is thought that the following somewhat unusual case is of sufficient clinical and pathological interest to justify its publication. When the patient first came under observation the clinical signs and symptoms had been present for two years, and were chiefly referable to the naso-pharynx, in which situation a hard swelling was present. There were, however, at this time some indications that the cranial cavity was also involved. When the patient was seen again three years later it was clear that the growth was causing marked pressure upon all the cranial nerves of one side, below and including the eighth. It is interesting to note that, although there was no actual involvement of the brain by the tumour, the man nevertheless presented marked and progressive dulling of perception, loss of memory, and general intellectual deterioration.

From the pathological point of view the chief interest lies in the nature of the growth, as to whether its origin was or was not in a "rest" of the notochord. It may be recalled that the chorda dorsalis is a specific embryonal tissue about which the spinal column develops. Portions of it commonly persist in the coccyx and in the junction of the sphenoid and occipital bones at the base of the skull. These portions occasionally give rise to small tumours, which in some instances increase considerably in size and assume malignant characteristics. The situation and naked-eye appearance of this particular growth, causing as it did marked absorption of the basi-sphenoid with extensions into the nasopharynx and posterior fossa of the skull, are highly suggestive of a chordoma. On the other hand, the histological appearance of stained sections is, on the whole, more closely akin to that of an endothelioma. While there is, perhaps, a certain amount of doubt as to the actual pathology, the probability is that it was a primary malignant growth of the naso-pharynx which, after involving the basi-sphenoid, extended into the posterior cranial fossa.

CLINICAL ACCOUNT

A cowman, aged 59 years, was sent to the out-patient department of the Royal Surrey County Hospital on June 2nd, 1927. He had complained of pain in the left temporal region and left side of the throat, deafness in the left ear, epistaxis from the left nostril, occasional vomiting, and loss of weight for the previous two years, and he was gradually getting worse. On examination he was generally wasted, sallow, and looked ill. There was ptosis of the left eye, and a hard swelling on the left side of the posterior wall of the pharynx, but no other abnormality. Wassermann reaction of the blood was negative. He was seen by Dr. T. B. Jobson, surgeon in charge of the ear, nose, and throat department, and by myself, and we were of the opinion that the condition was one of malignant and inoperable growth of the naso-pharynx. He was put upon local *x*-ray treatment, but after a short time discontinued attendance, and was not seen again for over three years.

On October 29th, 1930, I was asked by his medical attendant, Dr. Simpson of Farnham, to whom I am indebted for further notes, to take him into hospital, as he had become much worse, and marked cerebral symptoms had now appeared. It was stated that, in addition to his former complaints, for the past three months or so his voice had been husky, there had been difficulty in swallowing, and he had become dull and depressed mentally. On one or more occasions he had threatened suicide. On admission into hospital his condition was as follows.

Mental Condition.—He was correctly orientated, but there was marked intellectual deterioration with slow cerebration, dull perception, and loss of memory. It was impossible to elicit from him any accurate account of his illness, or to get him to co-operate satisfactorily in several tests.

Cranial Nerves.—I: So far as could be ascertained, olfactory sensation was not abnormal. II: There appeared to be a general impairment of vision, but the exact degree of this could not be determined. The edges of the disks were ill defined, and both disks were pale on the nasal sides, but there was no definite papilloedema. III, IV, and VI: The left pupil was smaller than the right; both reacted to light. There was marked ptosis of the left eyelid. It is considered that these signs were due to pressure on the ascending branch of the cervical sympathetic. The eye movements were normal, and there was no strabismus or nystagmus. V and VII: The muscles of the face and jaws appeared to be feeble, but there was no definite paralysis. VIII: Hearing on the right side was normal; a considerable degree of deafness was present on the left side, and the left drum was thickened and perforated, with projecting granulations. IX and X: There was paralysis of the left half of the palate and of the left side of the larynx, with extremely husky voice and difficulty in swallowing. Involvement of the vagus was further indicated by a rather rapid and irregular pulse, varying between 80 and 120, without any rise of temperature. XI: There was paralysis and marked atrophy of the left sterno-mastoid and upper part of the left trapezius muscles. XII: The left half of the tongue was paralysed, atrophied, and marked by deep furrows; the tongue deviated to the left on protrusion.

Spinal Nerves.—There was general wasting of all the muscles of limbs and trunk, but no localized paralysis. Sensation appeared to be normal all over the body. Knee, ankle, plantar, and abdominal reflexes were normal. There was no Rombergism, but the gait was ataxic and reeling, with a definite tendency to fall backwards and to the left.

General Condition.—The cerebro-spinal fluid, removed by lumbar puncture, was under slight pressure, but showed no pathological change on examination. Both the fluid and the blood gave negative Wassermann reactions. The systolic blood pressure was 190, but otherwise the circulatory, respiratory, alimentary, and excretory systems were normal. *X*-ray examination of the skull showed destruction of the body of the sphenoid bone from the posterior clinoid process to the level of the temporal bone (see Plate, Figs. 1 and 2).

Course of Illness

From the time of his admission the patient steadily deteriorated. The mental dullness became more marked; he suffered from frequent and severe headache in the left temporal and parietal regions; he had several attacks of profuse epistaxis from the left nostril; he vomited frequently; his voice became much more husky; and swallowing became increasingly difficult. Seven weeks after admission he developed pneumonia, from which he died five days later. Until its onset his temperature and respiration had remained practically normal during the time he was in hospital.

Diagnosis

It was considered that the patient had a tumour situated in the posterior fossa, chiefly on the left side, but the nature of this was uncertain.

Post-mortem Examination

A post-mortem examination made by Dr. J. Mark, my house-physician, and by Dr. Ruston, assistant pathologist to the hospital, revealed a growth about the size of a large but flattened egg between the dura and the bone in the posterior fossa of the skull, in front and mostly to the left of the foramen magnum. The position of the growth was such as to cause pressure upon the 8th, 9th, 10th, 11th, and 12th nerves of the left side, but the encephalon itself was not involved.

Dr. Mark and Dr. Ruston were at great pains to remove the whole of the bone to which the growth was attached, and Dr. Ruston has been good enough to write the following account of it.

PATHOLOGICAL ACCOUNT

It was only possible to make a limited examination of the skull. Upon removal of the brain in the usual way, there was exposed a soft, white, extradural tumour, compressing considerably the left half of the cerebellum and the medulla. This tumour appeared to be arising from the basi-sphenoid, spreading more to the left of the middle line than to the right, and extending down to the foramen magnum, where its lower border was turned under. Irregular in shape, it measured 1½ inches in its greatest length and 1¼ inches in its greatest breadth (less than 1 inch from the posterior clinoid processes). Its surface was lobulated, more so on the left side, where parts of it were raised half an inch above the neighbouring bone; its edge was similarly indented. No alteration in its consistency was made out, and nowhere was there any suggestion of bony or cartilaginous tissue. The dura was continuous over its surface, and no connexion was made out with any of the cranial nerves. A large vein issued from its surface about three-quarters of an inch from the lower pole; the lumen was free from growth.

The tumour was removed intact, together with the greater part of the basi-sphenoid, the anterior three-quarters of the foramen magnum, and the body of the first cervical vertebra. The pharyngeal aspect showed a small soft area of growth, which had penetrated right through the bone, but there was no other suggestion of pharyngeal origin, and a more complete examination was impossible. The specimen was decalcified and subsequently cut in the laboratory of University College, and then showed considerable absorption of the basi-sphenoid bone.

The naked-eye appearance of the tumour and its situation suggested the possibility of its being a chordoma; but the histological features were, on the whole, more like those of an endothelioma. Under the microscope there were masses of deeply staining endothelial cells within a fibrous stroma. These cell masses showed variations in the size and staining of the nuclei, in the packing together of the cells, and in the granularity of the cytoplasm. There were numerous large and multinucleate (giant) cells (3 to 6) with a paler cytoplasm. No cell nests or "epithelial pearls" were seen, and the fibrocellular stroma showed no inflammatory cells clustered together in defensive reaction.

MacCallum (*Textbook of Pathology*) gives a short note on chordomata, and speaks of their "lobules of groups and strands of large and small cells" which are rich in glycogen. The microscopical appearances of the present case closely resembled this description, and sections stained with iodine showed up the cell masses a deep brown. Ewing (*Neoplastic Diseases*), commenting on the difficulty of a positive histological diagnosis of chordomata, describes them as consisting of large, rounded, vacuolated, and hyperchromatic cells, and mentions a tumour described by Hassner measuring 5.5 by 6.5 cm., which produced symptoms over a period of four years. The clinical evidence in the present case points to a duration of over five years.

Professor M. J. Stewart of Leeds (*Journ. Path. and Bact.*, January, 1922) describes the chordomata as possessing an alveolar structure within a fibrous stroma, and stresses the importance of demonstrating mucin production in the multinucleate and vacuolated syncytial cells; he says, "the fully developed physaliphorous cell of Virchow is one ballooned with mucin." This condition I was not able to demonstrate satisfactorily in the present case, although with polychrome methylene blue the giant cells do take on a faint pink, and with orange G the granularity is more evident in the cytoplasm, and in places appears to stream out from the cells. It may be remarked, however, that in his article Stewart mentions a case described by Eitel in which mucin was absent and the cells were rich in glycogen. While, therefore, there are many features of this case which are suggestive of its being a notochordal tumour, the signs are not conclusive, and on the whole the evidence is in favour of its being an extending pharyngeal carcinoma. It well illustrates the difficulties of making a diagnosis between these two conditions.

I am indebted to Dr. Tredgold for the opportunity to examine this case, and at his request have written this note.

MENORRHAGIAS NOT DUE TO UTERINE DISEASE:

CAUSATION, CLINICAL FEATURES, AND TREATMENT *

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S.Ed.

GYNAECOLOGIST, ROYAL INFIRMARY; PHYSICIAN, ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL, EDINBURGH

(*With Special Plate*)

Cases of irregular and excessive uterine haemorrhage are divided into two main classes:—(1) Those in which the uterus is the seat of tumours (fibromyoma, mucous polypi and malignant disease) or retained fragments of placenta, and (2) those in which such a gross uterine pathology is absent and where instead there is nothing more than changes in the endometrium, usually of a proliferative nature, with commonly, in addition, some general and uniform overgrowth of the fibro-muscular wall of the uterus.

It is with the second of these two groups that this discussion is concerned. It embraces the majority of cases of bleeding uteri, and it includes the bulk of those cases which in the past have been described by such terms as chronic endometritis, chronic metritis, fibrosis uteri, and subinvolution.

ETIOLOGY

It is now some twenty years since Schroeder,[1] Beckwith Whitehouse,[2] the present writer[3] and others directed attention to evidence suggesting that many such cases owe their origin to disturbed ovarian function. In a paper published in 1913 and entitled "Uterine haemorrhage of ovarian origin" I gave reasons for the view that "where there is found on examination nothing abnormal except some uterine enlargement, and where the mucosa is found to exhibit the appearances of so-called 'glandular endometritis,' an ovarian source should be suspected."

It was Schroeder who, from the chaos of clinical and pathological data, first succeeded in building up a condition with some semblance to a separate entity which he has termed "metropathia haemorrhagica." Its main symptom is *metrorrhagia or irregular continued bleeding*, and, though occurring at any age from the menarche onwards, it is found characteristically between 40 and 50. Its pathology consists of a diffuse, often polypoidal proliferation of the endometrium with a hyperplasia and cystic dilatation of the glands, marked congestion of the vessels, free extravasation into the stroma and extensive endometrial necrosis. In a considerable number the muscular wall is increased as the result of a myohyperplasia. The ovaries exhibit characteristic changes in the shape of a cystic degeneration of the follicles and a failure of formation of corpora lutea and, according to Schroeder, the uterine changes and the consequent bleeding arise from this ovarian pathology. The views of Schroeder are supported in their general lines by Wilfred Shaw,[4] Graves,[5] and others. Shaw, for example, in 200 consecutive hospital cases of "dysfunctional" irregular bleeding found

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

53, or approximately 25 per cent., to fall into this category. On the other hand, Novak[4] has found hyperplasia and cystic glands in the presence of a fresh corpus luteum, and, moreover, in his cases exhibiting these changes, menorrhagia was more common than metrorrhagia or continued bleeding.

One of the most common types of dysfunctional bleeding is *polymenorrhoea* or too frequent menstruation, the periods becoming more or less stabilized to a shortened rhythm, often of 14 to 21 days. Prolongation and a quantitative increase of the flow are common accompaniments. Wilfred Shaw found this condition in 72, or 36 per cent., of his 200 consecutive cases of irregular bleeding, and where the ovaries were available for study found that the shortened menstrual rhythm was associated with a corresponding shortening of the follicular cycle in the ovary. In the endometrium no cystic or other characteristic change in the glands was present, but hyperaemia and oedema of the stroma were common. Other workers have described proliferative changes in the glands, and Novak and Graves have found the so-called "Swiss-cheese" cystic gland in this condition.

With regard to dysfunctional *menorrhagia*—an excessive or prolonged flow at normal intervals—Schroeder[1] believes the most potent factors to be hyperaemic states in the pelvis and inadequate contractility of the uterine muscle. On the other hand, many observers have postulated an ovarian aberration, and, although here there is no such direct evidence as is available in polymenorrhoea and the irregular haemorrhages, a number of workers have ascribed to ovarian dysfunction the abnormal endometrial changes frequently found in this condition (Novak, Graves).

Post-menopausal bleeding in a not inconsiderable number of cases is found in the absence of any gross uterine pathology, and to explain such cases as occur within a reasonably short interval after the menopause some observers have invoked an ovarian cause, either in the nature of a temporary "rejuvenescence" of the organ, or, where the bleeding is excessive, of structural degeneration in dormant follicles. A well-recognized though rare cause of post-menopausal haemorrhage is found in the interesting tumours which develop from the granulosa cells in the ovary and which induce active proliferative changes in the glandular and stroma elements of the endometrium. Such tumours are occasionally malignant. The possible relative frequency of ovarian causes of post-menopausal bleeding may be judged from the fact that in a consecutive series of 72 hospital cases we have found 11 instances in which all other factors have been excluded.

One of the most remarkable facts in connexion with the subject of dysfunctional bleeding is the infrequency with which in the literature we now find any reference to such conditions as chronic endometritis, chronic metritis, subinvolution, fibrosis uteri, etc., terms which, with their implication of an inflammatory and infective etiology, were in common use twenty years ago. Thus, Wilfred Shaw in his 200 consecutive cases found no pathology justifying the use of such terms as chronic metritis or subinvolution, and found only 13 cases of chronic interstitial endometritis. In all except one of these the symptoms, bleeding and leucorrhoea, were of recent duration. Graves in 257 cases of dysfunctional bleeding finds no place for a purely uterine pathology, and ascribes the various clinical conditions embraced under this heading to ovarian factors similar to those postulated by Schroeder, Shaw and others.

For the purpose of this communication we have studied 86 consecutive hospital cases, in whom the well-recognized causes of uterine bleeding—tumours, malignancy, placental fragments, tubo-ovarian inflammation, etc.—have been excluded. In all the cases the endometrium has been obtained for examination either by curettage or after hysterectomy (4 instances), whilst in two of the latter the ovaries were available.

It has been found convenient to arrange the cases in the following clinical groups (Table II):—

(1) *Menorrhagia*—13 cases, ranging between the ages of 20 and 50, with the maximum incidence falling between 35 and 50.

(2) *Polymenorrhoea*—28 cases, the maximum age being 52, the minimum 19, with the chief incidence falling between 30 and 50.

(3) *Arrhythmic and Continuous Bleeding*—39 cases. The bleeding corresponds to a metrorrhagia or to a continued loss extending beyond the confines of a menstrual cycle. The youngest patient was 21, the oldest 53, whilst 23 out of 39 cases were in women over 40 years. Clinically these cases may be subdivided into those where the metrorrhagia or continued loss was preceded by a history of (a) menorrhagia—2 cases; (b) polymenorrhoea—14 cases; (c) amenorrhoea—12 cases; or where (d) there was no previous menstrual abnormality—11 cases.

(4) *Post-menopausal Bleeding*—6 cases, the oldest patient being 70, the youngest 48.

With the object of elucidating etiology (1) the endometrium has been studied in all the cases and, as the relation of (2) childbirth and of (3) incidental organic disease is so prominent in the histories as seemed to warrant a closer study, these questions have also been brought under special survey.

THE ENDOMETRIUM

It has been claimed by some observers that there is a correlation between clinical features and endometrial pathology and that on this basis we can construct certain entities with a more or less constant symptomatology and ovario-uterine pathology.

TABLE I

SHOWING RELATIONSHIP BETWEEN THE CLINICAL TYPE OF BLEEDING AND THE CHANGES IN THE GLANDS OF THE ENDOMETRIUM

	No Abnormality	Hyperplasia	Hyperplasia with Cystic Change	Total
Menorrhagia	4	4	5	13
Polymenorrhoea	10	4	14	28
	—14	—8	—19	—41
Continuous Bleeding (and metrorrhagia):				
1. Preceded by menorrhagia	1	1	0	2
2. Preceded by polymenorrhoea	2	0	12	14
3. Preceded by amenorrhoea	1	0	11	12
4. With no previous menstrual abnormality	2	1	8	11
	—6	—2	—31	—39
Postmenopausal bleeding	2	1	3	6
	22	11	53	86

The investigation of the present material does not accord with this view, and in Table I, where the gland changes in the endometrium are grouped according to clinical type, it will be seen that there is a considerable overlapping within the several groups. One of the most interesting features revealed is the very high frequency of cystic hyperplasia in the cases of metrorrhagia and continuous bleeding (31 in 39 or nearly 80 per cent.). On the other hand this feature is present in no less than 19 out of 41, or over 46 per cent. of the cases where the menstrual function is more or less regular. It is true that the most excessive changes of this kind have been found in the former group, but the findings indicate that some of the characters of the Schroeder complex are shared by cases in which a more or less regular ovarian rhythm is present (Plate, Figs. 1 to 4). As it has been my routine practice for a considerable number of years to treat dysfunctional bleeding by conservative measures this series contains only 2 cases in which the ovaries are available for examination. In one, a case of 14 weeks' continuous

bleeding in a woman, there was bilateral cystic follicular disease and no active corpora lutea. The uterus, removed at the same time, had the Schroeder pathology in a marked degree (Fig. 5) In the other case, there was a blood cyst of the corpus luteum in a woman, aged 39, in whom the uterus was removed for excessive polymenorrhoeic bleeding. In only 1 out of the 86 cases did the endometrium exhibit the appearances of chronic interstitial endometritis.

RELATION TO CHILDBIRTH OR ABORTION

In the second column of Table II there are stated opposite the various clinical types the numbers in which the symptoms were directly dated back to a childbirth or abortion.

TABLE II.

SHOWING CORRELATION BETWEEN IRREGULAR AND EXCESSIVE UTERINE BLEEDING AND (*a*) CHILDBIRTH AND ABORTION, AND (*b*) GENERAL ORGANIC DISEASE.

	Total	Dating from Childbirth or Abortion	General Organic Disease in Remaining Cases
Menorrhagia	13 } 41	6 } 26 (63.4%)	2 } 8 (19.5%)
Polymenorrhoea	28 }	20 }	6 }
Continuous Bleeding (and Metrorrhagia):			
1. Preceded by menorrhagia	2 } 39	0 } 7 (17.9%)	2 } 21 (53.8%)
2. Preceded by polymenorrhoea	14 }	5 }	5 }
3 Preceded by amenorrhoea	12 }	0 }	10 }
4. With no previous menstrual abnormality ..	11 }	2 }	4 }
Post menopausal Bleeding ..	6	0	0
	86	33	29

It will be noted that out of 41 cases of menorrhagia or polymenorrhoea this correlation is present in 26 or 63.4 per cent., whereas it exists in only 7 out of 39 or 17.9 per cent. in metrorrhagia and continued bleeding. The figures though small are suggestive. In the present state of our knowledge any interpretation of this discrepancy must be largely conjectural, but the first factor to thrust itself forward in this connexion must naturally be infection. That there is such a background is supported by the correlation of chronic cervicitis, a lesion which is known to be one of the commonest infective sequelae of childbirth and which is, at the same time, one of the easiest to recognize.

Chronic Cervicitis.—In previous papers I have referred to the frequency with which this lesion is associated with menstrual irregularity and excess. Masson and Parsons,[8] Jeff Miller[9] and Behney[10] have referred to the same fact. In a consecutive series of 177 cases, in which chronic cervicitis was the sole recognizable lesion in the pelvis, we have found menorrhagia in 53 and polymenorrhoea in 58, a total of 111 or 62.7 per cent. Further, in such cases the endometrial changes are similar to those present throughout the dysfunctional haemorrhages and, moreover, as I[11] have elsewhere shown, the menstrual excess is often cured by treatment directed solely to the cervix. These findings are in keeping with the view that the cervical disease provokes the bleeding through the medium of an ovarian dysfunction.

GENERAL ORGANIC DISEASE

The correlation of this factor is shown in Table II, where it is seen to fall most markedly in those cases of graver blood loss, in which the factor of childbirth is less apparent, just as if we were being brought face to face with two main competing and alternative influences in etiology. In the milder group general organic disease is found in a ratio of 19.5 per cent., whereas with severe dysfunction the ratio rises to 53.8 per cent. The significance of this finding is revealed, for example, by an enumeration of the organic diseases present in that group in which there is continued bleeding preceded by a period of amenorrhoea. Here the ratio was 10 out of 12. Seven suffered from one each of the following: severe hypertension, recent pleurisy, severe pyuria, bronchitis, tuberculosis of the lung, gonorrhoeal infection, and rheumatism; 2 had severe gastro-intestinal disturbances, whilst 1 had rheumatism and recurring haematemesis. In Table II it should be noted that for purposes of clearer demonstration column three refers only to those cases which remained over after the childbirth relation had been extracted. For this purpose this relation was considered as primary. The figures as so given leave undecided, of course, the question as to how far the childbirth relation may in its turn be affected by coexisting organic disease.

Our etiological survey has shown the need for discarding the older view which sought to explain excessive and irregular dysfunctional bleeding on the basis of a purely uterine pathology. It is true that there still remains an ill-defined group in which infection of the endometrium plays a direct part, but it would seem that in such the bleeding is of short duration and is prone to spontaneous cure, for these cases constitute a strikingly small proportion of the more severe cases which enter hospital for treatment and which comprise the material used for purposes of investigation.

At the same time, whilst there is clear evidence on which to begin to erect a new etiology based upon a reciprocal interplay between ovary and uterus, we do not yet possess a sufficiently sound foundation in physiology to justify more than tentative views. The primacy of the ovulation and corpus luteum cycle, for example, to which in the past supreme importance has been attached, has been undermined by the discovery by Corner,[12] Van Herwerden,[13] Hartman,[14] and others, that in monkeys, and occasionally also in man, menstruation can occur normally in the absence of ovulation. These observations are in keeping with the demonstration by Parkes,[15] that in the mouse, after ablation of the follicular apparatus in the ovary by means of *x* rays, the oestrous cycle can continue. I[16] have discussed the significance of these facts in a recent paper, and have indicated that the oestrous cycle and the periodic function of menstruation must depend upon some rhythmic ovarian activity which is separate from the follicular cycle. From this standpoint we may conjecture that the various diseased states of the follicular cycle and of the endometrium associated with irregular bleeding are in the nature of secondary phenomena that merely accompany some more basic ovarian aberration that itself is primarily responsible for provoking the bleeding.

The cause and nature of the ovarian disturbances are still obscure. It would seem clear that childbirth and organic disease are prominent factors. It is legitimate to conclude that direct damage of the ovary by inflammation or tumour growth may sometimes operate. In this way we may explain the bleeding associated with tubo-ovarian infection and granulosa cell and other tumours of the ovary. In view of the primary part played by the anterior pituitary in the activation and periodicity of the ovary it is possible that disturbance of this endocrinal balance may sometimes be operating. In this connexion Hofbauer[17] claims to have induced changes in the ovary and endometrium of guinea-pigs similar to those present in the Schroeder syndrome by administering anterior pituitary experimentally.

DIFFERENTIAL DIAGNOSIS IN IRREGULAR AND EXCESSIVE UTERINE HAEMORRHAGE

In a large number of cases the history of bleeding with the absence of any gross recognizable lesion allows of a diagnosis being made with approximate accuracy. The irregular bleeding of young girls is generally due to ovarian

dysfunction, but, with increasing age, the frequency with which other factors operate may make the diagnostic diagnosis more difficult As the bulk of the cases fall between the ages of 30 and 50, when cancer and fibroids compete so largely, the need for an immediate and complete investigation in such patients is specially urgent, and the same applies to bleeding beginning for the first time after the menopause when malignancy, usually in the cervix, more rarely in the uterine body or ovary, is the most frequent single factor present

Where physical examination fails to reveal the presence of an adequate explanation of the bleeding, such as fibromyoma, cervical cancer, a polypus projecting from the cervix, or an inflammatory mass in the tubo-ovarian region, it may be laid down as a rule that curettage is the first step in the diagnosis Bleeding in the teens is the only exception to this rule, and in such cases treatment may usually be commenced forthwith on a clinical diagnosis

We have seen that a considerable number of cases of ovarian dysfunctional bleeding may have a preceding period of amenorrhoea, and in such the exclusion of the pregnancy factor is often possible only after curettage and the discovery of the cystic endometrial changes so characteristically found in this class of case

TREATMENT

Until we have arrived at a more precise understanding of the ovarian factors, it is inevitable that our treatment of such dysfunctional bleeding must be largely symptomatic It is true that therapeutic claims are advanced on behalf of many of the commercial ovarian preparations, but these claims have little foundation in science and, for the most part, equally little sanction in practice In 23 intractable cases of excessive and irregular bleeding in my department the effect of a concentrated dosage of some of the commercial ovarian products of proved activity—and of these sistomensin has been chiefly employed—has been carefully studied by Dr W P Kennedy Cure of the symptoms is reported in 3 and marked improvement in 5—a total positive result of 10 in 23—and it is interesting to note that in 7 of these cases an associated dysmenorrhoea for which in fact, the treatment was initiated has simultaneously responded to the measure

There is a steadily increasing literature in regard to the results of the treatment of dysfunctional uterine bleeding with ovarian or placental extracts Thus, Campbell and Collip[10] have recently recorded success in the treatment of metrorrhagia with the anterior pituitary like principle of the placenta Many however, of these records deal with the use of experimental material prepared in the worker's own laboratory

A finding of considerable moment in regard to the treatment of these cases is the relief, both immediate and permanent, which may follow the diagnostic curettage Thus, out of the 86 cases specially studied for this paper, in all of which curettage was done the notes record "cure" of the bleeding in 11 (menorrhagia 3, polymenorrhoea 5 and continuous bleeding and metrorrhagia 2) It is true that cauterization of a chronically infected cervix was carried out at the same time in 4 of the cases

In the case of intractable bleeding which fails to respond to the above conservative measures, we are constrained to adopt more drastic methods, and, of these, the choice lies between hysterectomy and radium or *x* rays sterilization These measures are frequently called for, especially in the intractable dysfunctional bleeding of women between 40 and 50 It is now my practice in such cases to induce an artificial menopause by introducing radium into the uterus or by exposing the ovarian region to three successive doses of *x* rays In the present series hysterectomy was carried out 4 times, radium was employed 14, and *x* rays 5 times

SUMMARY

1 Except after a recent childbed infection or gonorrhoea inflammation of the endometrium or myometrium is a rare cause of irregular and excessive uterine bleeding

2 There is evidence that in a large majority of such cases the uterine pathology—the endometrial proliferation and congestion and the myohyperplasia—and the symptoms are dependent upon aberration in the ovarian function The most common recognizable causes of this aberration are childbirth and general organic disease

3 The terms chronic endometritis, chronic metritis, fibrosis uteri and subinvolution applied to the pathology found in irregular and excessive uterine bleeding are, therefore, inappropriate

4 The diagnosis in such cases rests upon an absence of a gross pathology—tumours placental remains tubo-ovarian inflammatory masses etc and the appearances found in the endometrium after curettage

5 The treatment consists of curettage ovarian therapy or in intractable cases of the use of sterilizing doses of radium or *x* rays

PHYSIOLOGICAL ASPECTS OF MENSTRUATION*

BY

A S PARKES M A, D Sc Ph D

HONORARY LECTURER AT UNIVERSITY COLLEGE LONDON, FULLERTON STUDENT OF THE JOINT SCHOOLS

In opening this discussion on menorrhagias not due to uterine disease I am very conscious of the fact that my own knowledge does not extend to the clinical aspect of the problems involved I would wish, therefore, to take up the standpoint of the experimental physiologist, and to discuss some facts which may be of assistance in analysing the human menstrual cycle, and therefore of assistance in considering disorders caused by physiological deficiency or excess

In an endeavour to homologize the menstrual cycle of primates with the oestrous cycle of lower mammals we may first consider certain of the fundamental processes involved in the latter In lower mammals the ovarian cycle consists essentially of two phases—first the phase in which the Graafian follicle undergoes maturation and finally ovulates, and secondly the phase in which the corpus luteum develops from the shell of the ruptured follicle In most species only minor changes take place in the uterus during the first of these ovarian phases the so-called oestrous phase more obvious changes occur in the vagina changes that facilitate copulation which is restricted to this period In the second ovarian phase—the so-called luteal phase—marked changes take place in the uterus These changes vary in degree and kind in

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association Eastbourne, 1931

different species, but the end-result is the same—namely, the uterus is prepared by an increase in its physiological sensitivity, with or without proliferation of the endometrium, for the reception of the fertilized ovum. In the mouse and rat the development of the corpus luteum required to produce the characteristic pre-gestational changes in the uterus is only attained after copulation, while in such animals as the rabbit and ferret copulation is necessary to cause ovulation.

From our present point of view the most interesting feature of this pre-gestational development of the endometrium is its behaviour when the animal fails to become pregnant—in other words, when the prepared endometrium is found to be unnecessary. In all animals so far known, retrogressive changes take place in the prepared endometrium when pregnancy fails to supervene, and the degenerate mucosa returns after a period of time to normal. The severity of the process of destruction of the developed endometrium varies in different species, and does not appear to depend upon the extent of the previous endometrial development.

In the rat and mouse, following sterile copulation, the morphological changes in the uterus are slight compared with those found in some other species, and the subsequent process of destruction is comparatively mild. In extreme cases a certain amount of intercellular haemorrhage is found which may lead to the appearance of small haematomata under the epithelium, but haemorrhage into the lumen rarely occurs. In the guinea-pig during the luteal phase the morphological change in the uterus is again slight. In the rabbit a very considerable degree of pre-gestational proliferation occurs after ovulation. In this species the development consists very largely of glandular proliferation, and at the end of ten days after ovulation the uterine endometrium is honeycombed with large glands opening out into the lumen. The destruction of this development in the rabbit is carried out by a process of retrogression of the glands and sloughing of the epithelium. Thus, 18-20 days after ovulation, the lumen is found to contain large multi-nucleate giant cells formed by the conglomeration of debris from the epithelium. In the rabbit, however, this extensive process of destruction is associated with little or no haemorrhage, and red blood corpuscles are rarely found in the lumen. A similar, though more prolonged, period of pseudopregnancy is also found in the ferret. In the dog, pseudopregnancy lasts 6-7 weeks, and is followed by uterine retrogression resulting in a variable degree of haemorrhage into the stroma. In various other animals, post-ovulation development and retrogression of the uterus have also been studied.

It may be said, therefore, that in known species of lower mammals the uterus exhibits a tendency to undergo breakdown of the endometrium at a certain definite phase of the cycle, namely, at the end of the phase of development carried out in preparation for the reception of the fertilized ovum. There is, however, one other phase of the cycle in which certain animals, at any rate, appear to undergo some destruction of the endometrium. In the dog haemorrhage into the uterine lumen is found in the immediate pre-ovulation phase, and in this case the actual haemorrhage is more pronounced than that found at the end of the subsequent pseudopregnant period. Thus, external bleeding may continue for as much as ten days in the pro-oestrous dog. A similar, though less extensive pre-ovulation destruction of the uterus may also occur in such animals as the cow.

In attempting to interpret the human menstrual cycle in the light of these facts relating to lower mammals, it is necessary to consider the one salient point which occurs in the human, namely, the period of menstruation. Taken in conjunction with what is known of lower mammals, two alternative theories could be evolved: (a) that menstruation is a pre-ovulation phenomenon similar to that occurring in the dog but more intense, or (b) that human menstruation is an exaggerated homologue of the pseudopregnant breakdown found in many of the lower mammals.

Regarding menstruation as a pro-oestrous phenomenon, the haemorrhage would precede the ovulation of the same cycle, and therefore at puberty the first menstruation would precede the first ovulation. Regarding it as an end-of-pseudopregnancy phenomenon, menstruation would follow ovulation of the same cycle, and therefore the first ovulation would precede the first menstruation. The time of ovulation in the human cycle is now generally agreed to be some 13-17 days after the beginning of the previous menstruation, and therefore to fall about midway between two menstrual periods. On this evidence, therefore, the pseudopregnancy theory of menstruation would appear more probable. On such an interpretation ovulation takes place, the corpus luteum develops in the ovary, and pre-gestational changes take place in the uterus. Then, when pregnancy fails to supervene, retrogressive changes occur in the corpus luteum, the endometrium breaks down and menstruation occurs. In other words, menstruation is the removal of an unwanted proliferation of the uterus, and occurs, therefore, because conception has not taken place. On this view, alone, however, menstruation would be dependent upon the preliminary development of the corpus luteum in the ovary, and it is now well known that menstruation will occur in the absence of ovulation. Since it is known that the oestrous changes of the accessory organs of lower mammals may occur without a morphological cycle in the ovary, this fact, of course, favours the view that the breakdown involved is pro-oestrous in nature.

Fortunately, however, it has been possible to turn to the lower primates for investigation of this problem. All Old World monkeys appear to menstruate and to have a cycle essentially comparable to that occurring in the human. On the other hand, many of them also have an obvious external sign of the time of ovulation, and to this extent more closely resemble the lower mammals. Such monkeys, therefore, are extremely valuable in any attempt to homologize the sexual cycle of man with that of the lower mammals. In the baboon, for instance, the follicular phase, during which the development of the Graafian follicle takes place, is characterized by the appearance of an enormous swelling of the vulva and pudendal region. At the end of the follicular phase, when ovulation takes place, this external swelling undergoes a sudden subsidence and is reabsorbed within about two days. About 10 days later, a period of menstruation of the usual type appears.

The start of the cycle in the baboon, either at puberty or following a period of lactation, is characterized by the appearance of the external swelling, and there can be no doubt whatever, therefore, that in this animal the *follicular phase occurs and passes away some* time before the onset of the corresponding menstruation. It is thus possible to say that the latter is not a straightforward *pre-ovulation phenomenon. On the other* hand, when the monkey fails to ovulate, the same external sign of the follicular phase appears, followed by menstruation as usual, and the total length of the cycle, as well as the time relations of the phases, is the same as in the normal ovulating animal. There is, however, one important difference between the uterine cycle in the ovulating and in the non-ovulating monkey, namely, that the typical pre-menstrual development of the uterus only occurs when

the corpus luteum is present in the ovary. Where ovulation has not taken place menstruation though occurring at the normal time, takes place from an undeveloped resting endometrium. It is thus necessary to suppose that where as the pre-menstrual development of the uterus is dependent, as would be expected, upon the presence of the corpus luteum, the actual factor causing necrosis and breakdown of the epithelium is not set in action by the atrophy of the corpus luteum although operating at the same time, and is independent of any morphological ovarian cycle.

Evidence has lately become available as to the site of origin of the substance concerned. Some years ago it was shown by Allen that menstruation could occur in *ovariectomized monkeys after a series of injections of oestrin*. Since the hormone is associated with the follicular phase of the cycle in the normal animal these experiments appeared to simulate the condition of affairs found in the non-ovulating monkey. Very recently, however, Hartman has shown that this effect of injection of the ovariectomized monkey is completely lacking if the animal is hypophysectomized. It is thus necessary to suppose that Allen's results were due to activation of the pituitary body by the injection of oestrin, and that the substance causing necrosis of the endometrium is probably hypophyseal in origin.

The importance of studying the nature of this factor causing necrosis has been emphasized for some years by Shaw, and it seems probable that further progress with the study of the *mechanism of the human menstrual cycle* will be dependent upon some working hypothesis of the factor involved in the necrosis of the endometrium. From the point of view of the subject under discussion, namely, *the factors concerned in menorrhagia* unaccompanied by uterine disease, it is quite evident that this necrosis factor is of prime importance. In cases of menorrhagia, the morphological cycle in the ovary may be abnormal or *even entirely suppressed, and a condition may be found* analogous with that in the non-ovulating monkey except that the period of destruction of the endometrium is prolonged indefinitely. This would appear to point to the possibility that the factor causing necrosis loses its normal cyclic activity and functions persistently. If such an explanation can be substantiated an important basis will have been found for the experimental attack upon the problems of menorrhagia.

VARICOSE ULCER*

BY

A. DICKSON WRIGHT, M.S., F.R.C.S.

ASSISTANT DIRECTOR SURGICAL UNIT ST. MARY'S HOSPITAL; ASSISTANT SURGEON PRINCE OF WALES HOSPITAL

(With Special Plate)

The femoral artery delivers a very large quantity of blood to the leg every twenty four hours, probably more than a thousand pints. The arterial blood is delivered with all the force of the heart and gravity behind it, but when this force is dissipated in the capillary bed there comes into play a *wonderfully complicated mechanism* whereby this large volume of blood is returned to the heart against gravity. Let there be a drop in efficiency of one part in *two hundred* in this return mechanism, and serious changes will occur in the leg.

Many factors assist in the return of the venous blood, such as the elasticity of the skin, the contraction of the leg muscles, abdominal and thoracic aspiration, *vis a tergo* of capillary pressure, *muscular tone and contractions of* the vein walls, and the elaborate valving of the veins.

Of this group it is fairly certain that the last two factors are the most important. Should the veins become incompetent to return the blood to the heart from blockage, atony of their muscular coats or failure of the valves, serious stagnation phenomena will result, and that naturally in the region most remote from the heart, because here the effect of gravity is at its maximum. The support of shoes and boots and the pressure on the soles prevent oedema and stagnation in the feet. Figures 1, 2 and 3 show the regions in which ulcers develop according to the type of footwear worn. The upper confine of this ulcerative region is constant, and the lower corresponds to the limits of foot support. By a simple consideration of this area which carries probably 99 per cent. of the indolent ulcers affecting mankind, we see *both the cause* and the proper line of treatment. The final cause in all cases is gravity, which is too much for the legs of erect standing mankind and the best treatment is *constant support*.

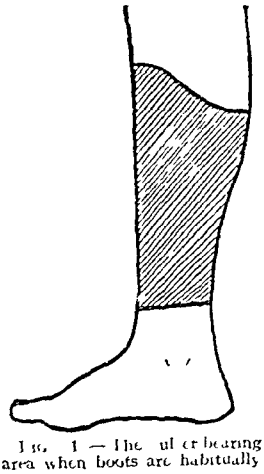

FIG. 1.—The ulcer bearing area when boots are habitually worn.

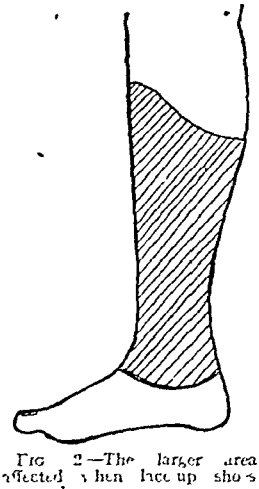

FIG. 2.—The larger area affected when lace-up shoes are used.

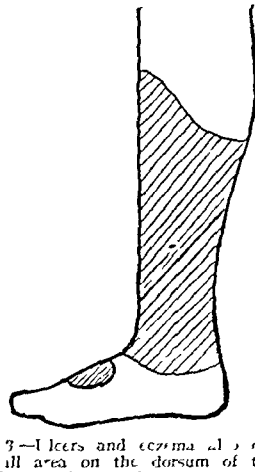

FIG. 3.—Ulcers and eczema also occur in the small area on the dorsum of the foot when shoes with a single strap are worn.

The name varicose ulcer is an oxymoron and is not comprehensive enough because *many of these ulcers have* other causes such as venous thrombosis, ankylosis of joints, paralysis of the leg muscles, lymphatic blockage, etc. *More comprehensive* descriptions are ulcus cruris, indolent ulcer of the leg, chronic leg ulcer, stasis ulcer,

*Read in opening a discussion in the Section of Dermatology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

static ulcer, and the term that I have suggested, namely, gravitational ulcer.

The necessity for support for swollen legs was probably discovered many hundreds of years ago, and it is impossible to trace the originator of this very obvious principle, which, nevertheless, seems to be forgotten by so many. A study of the vast literature on this subject reveals literally hundreds of methods of treatment advocated, which neglect this one vital essential to every line of treatment. All efforts seem to have been concentrated on finding a magical salve, powder, or even gas, which would stimulate waterlogged tissues into healing. Nearly every chronic disease, and many acute ones, have some mechanical obstacle, which hinders Nature in her powers of overcoming infection, and the removal of this obstacle should be the first consideration in every such disease whether it is the muscle spasm of gonorrhoeal ophthalmia or anal fissure, or the faulty hydraulics of a "milk leg."

TREATMENT OF CHRONIC ULCER OF THE LEG

Chronic ulcer of the leg has certain features which impose limitations to the type of the treatment employed. First, its most common complications are poverty and fecundity, so the treatment must be such as not to involve hospitalization, as the mother of a poor-class family must look after her children; and, moreover, it must not be too expensive. Secondly, the disease is very common, and it requires many doctors to treat all the cases in existence, so that the treatment must be simple and within the reach of all medical practitioners, and not too laborious and time-consuming. It is of the utmost importance that the treatment of varicose ulcer should not be left to district and out-patient nurses. Thirdly, the treatment must not be too tiresome or painful, or the patient will prefer the disease to the treatment; and if the treatment is bravely borne, only for the ulcer to relapse, the recurrence assumes the dimensions of a calamity in the mind of the patient, who then becomes sceptical of all kinds of treatment.

The treatment I adopt for this difficult disease is simplified as far as possible. It is ambulant, and the patient's employment is not interrupted. The visits to hospital are at intervals, on the average, of three weeks. The ulcer is dressed with nothing but its own discharge, so that unnecessary labour and expense are avoided; more important, the efficacy of the support is not interfered with by the repeated necessity of dressing the ulcer. The bandage used to support the leg is of elastic sticking plaster, so that it cannot move when once applied, and it adjusts itself to the shrinkage of the leg. Another advantage of this adhesive plaster is that it is, to a certain extent, waterproof, allowing restricted bathing, and, more important, keeping the discharge in, and thus saving changes of dressing. Owing to the elastic nature of the bandage, it can be wound on smoothly in a continuous spiral; this takes much less time than the method of applying separate strips of ordinary adhesive. In large ulcers, skin grafts are buried in the granulations by insinuation of small implants, by darning in threads of skin, or by injecting suspension of skin in saline, but this makes no difference to the method of dressing. The sticking plaster is used just the same, and the skin grafts seem to be invariably successful.

All through it is remembered that the ulcer is not the condition being treated, but an underlying stagnation of the venous blood, lymph, and tissue fluid. If this is due to varicosity of the veins, these are treated by injections of sodium morrhuate.

Ligations of large penetrating veins and venous cysts are done in severe cases, because the cure of these cases by injection is very difficult, and recurrence of the varicosity common. These ligations are performed in the out-patient department, as the whole treatment must be ambulatory, no beds being available in hospital for these cases. In the other cases, where there is venous obliteration, or other cause of indolent ulcer, steps must be taken to ensure that the patient will have continuous support over a long period of time.

Here arises the very important question of the treatment of the varicose veins which develop after deep thrombosis of the puerperium, typhoid fever, etc. It is customary to abstain from injections in these cases, but I have gradually ignored this contraindication, and have now treated 56 cases of ulcer associated with old "white leg"; in 42 of these, large varicosities were injected, and in the remaining 14 there were not present any varicose veins. In addition to these, a large number of similar cases have been injected suffering from periphlebitis or swelling, but I have never seen any damage result in the shape of increased swelling, cyanosis of the limb, etc. In cases of damage to the deep circulation, I regard these superficial varicose veins as an added embarrassment to the sound veins which are transmitting blood in the upward direction.

Contraindications

As regards contraindications to this method of treatment, there are only two—namely, associated arterial disease and diabetes. I have observed (and this is a most important point) in legs which have been damaged by long-standing venous stagnation that, if gangrene supervenes as a result of senile or diabetic arteritis, it is not the toes which are affected first, but the area of skin outlined in Figures 1, 2, and 3. Treatment by compression would in these cases be disastrous, and one must always be on the look out for them. The other complications of varicose veins—eczema, phlebitis, periphlebitis, pedal deformity, periostitis, arthritis, etc.—are nearly all benefited by this treatment, and their presence should not dissuade one from practising any part of the treatment—compression, injection, or skin grafting.

Disadvantages

The disadvantages of this method of treatment are:

Failure.—Many cases are referred to me because the treatment has been ineffectual, but I have never failed to bring about rapid healing in these cases. The almost invariable cause of failure is the looseness of the bandage; the patient is always astonished at the force I employ, and delighted with the relief afforded. Another cause of failure is the delegating of the bandaging to those who do not understand the principle of the treatment. In one case referred to me of a very severe ulcer, following a badly placed incision for cellulitis of the leg, in which I was informed that my type of treatment had done more harm than good, I learned that the adhesive plaster had been applied on the leg *above* the ulcer by the out-patient sister, the ulcer and foot being left out to swell, in order that hot fomentations could be applied four times daily to the ulcer. Other cases of failure I have seen have been due to syphilis or malignant disease, and I have come to regard the lack of response of an ulcer in the former case to be more certain than the Wassermann reaction in making a diagnosis. In malignant disease, of which I have seen two cases, failure to react to the treatment made the diagnosis clear.

Eczema develops under the adhesive in about 5 per cent. of cases, and seems to be an idiosyncrasy. In about 1 per cent. of cases the eczema becomes generalized, affecting chiefly the face and arms. The idiosyncrasy may be to rubber, zinc, or to the morrhuate injections. It is a serious disadvantage when it occurs, especially when it is of the exudative type, and causes great dismay to the patient. I have only once stopped treatment on this

account, and in that case the patient was in a lunatic asylum. In many cases I have persevered in the face of distressing eczema, with the most gratifying results. *Per contra*, I have found the most severe "stocking" eczemas, which had been treated by other methods for a long time, immediately improve with elastic compression. I have had adhesive bandages made, impregnated with rivanol 1/1,000, ichthyol 5 per cent., aluminium acetate 5 per cent., for these cases, and a change to one or other often checks the development of an eczema.

Blisters develop under the bandage, and burst and ooze quantities of fluid. They are often on the sole of the foot, and cause a fair amount of pain and discharge, and the base looks as if it would form a new ulcer, but I have not found that this occurs. I never stop the treatment because of the development of blisters.

Cutting of the bandage into the skin produces linear ulceration, and is due to faulty bandaging in very oedematous legs. It is avoidable by placing longitudinal strips up the leg as splints, and by overlapping each turn of the bandage two-thirds of its width by the ensuing turn.

Pain is sometimes increased at first by the pressure. I find this in only 10 per cent. of cases, the remaining 90 per cent. of the patients being very much gratified by the comfort afforded. The pain may be due to blisters or faulty application of the bandage, or to the injections. In certain cases it is in the bones or joints adjoining the ulcer, and in some cases in the ulcer itself; to avoid this latter pain I increase the pressure over the ulcer by sorbo rubber pads, with adhesive on one side, stuck on over the ulcer on the bandage and then pressed into the ulcer bed with another turn of the bandage. These pads are especially valuable in treating ulcers lying in the sulcus under the malleoli where the bandage does not grip very tightly. The sprinkling of aspirin powder on the floor of the ulcer I have found an excellent analgesic, lasting from four to seven days. Finally, a night powder of a barbiturate and aspirin is a great and justifiable help at the start of the treatment. It saves the patient from worrying during the long night hours over an ulcer, the constant companion for many years, now cut off by sticking-plaster. She has fed the ulcer with salves, antiseptics, lint and gauze for so long that she thinks that terrible things are happening under the bandage.

The Mental Attitude of the Patient

The mental attitude of the patient is sometimes difficult, and in nearly all cases has a financial background. In these days of humane government, chronic bronchitis in the husband and a varicose ulcer in the wife will maintain a family in certain parishes, and these valuable diseases will not be parted with too easily. Again, pensions are awarded for ulcers acquired in the Army, and there is a certain type of man who will on no account give up this premium on ill-health. In Central Europe large ulcers of the leg are exposed in the streets for begging purposes, but this is only a degree more degrading than other ways of using ulcers as a source of income. Fortunately, I have found this type of thing very rarely, and then nearly always in men; as a rule, every patient is desperately anxious to get the ulcer healed.

Expense and Difficulty of Treatment

Expense of treatment should be a very minor consideration in this disease, which is of great economic importance. I have scores of cases of men—mechanics, painters, and so on—who have lost in wages hundreds of pounds, and have cost the Government, health clubs, and hospitals equally large sums of money; these men were all very anxious to get to work and maintain their families. The bandages are fairly expensive, and the 75 pints of sodium morrhuate which I inject annually cost a certain amount, but it is found that the patients' contributions more than cover the costs. A great argument against too cheap a treatment is that it will fall into the hands of nurses, and we shall have a repetition of Unna's bandages applied year after year to the same quota of patients, without any effect at all.

Difficulty of the treatment is used as an argument, but if good bandaging and injection technique are once learned, it is very easy, and the knowledge so acquired is useful in many other ways. I have found that those who have mastered the method by attending the clinic have always succeeded in getting the same excellent results themselves.

Relapse is a most irritating argument against any treatment. It is better to be without a disease for even a short time than to have it all the time, moreover, in this disease it is easy to prevent the recurrence, if it is anticipated. In 525 cases of cured ulcer, I have only had 18 relapses (3·4 per cent.) in the last three years. *None* of these was difficult to treat.

The following cases illustrate the method of treatment of two typical difficult cases:

Case I

For eight years Mrs. R. suffered from ulcer below the internal malleolus of the left foot. It was small and deep, the size of a shilling, but intensely painful, the type of ulcer known as Corlette's irritable ulcer. Owing to the pain the patient walked on the outer border of the front part of the foot, and had a fixed talipes equino-cavo-varus deformity as a result. She was sent to me because the practitioner could make no headway with elasto-plastic bandaging, or any other treatment. There had been a tendency not to persist with any single line of treatment long enough for it to do good, and I felt that it was the patient, a strong-minded woman, who was ordering the treatment. No varicose veins could be seen or felt, and the leg did not seem greatly swollen. A bandage was wound on with a pressure that exasperated the patient, and a small rubber adhesive pad laid over the ulcer and bound tightly on to it, a sleeping powder was prescribed, and the patient returned in a week. She had been much more comfortable, and the ulcer was now flush with the surrounding skin, and definitely healing. The pressure had pushed a lot of oedema out of the leg, and a varicose saphenous vein was now injected easily. The bandage was re-applied as tightly as before, and the sleeping powder omitted. The next time a small deep vein was injected above the ulcer, and in four weeks the ulcer was healed firmly, the total cost of materials being twelve shillings. The support is being kept up by a bandage for six weeks; an elastic stocking will follow, to consolidate the cure, and finally the question of operation for the deformity will have to be discussed with the patient.

Fig. 4.—The ulcer facies.

Case II

Mrs. C., aged 51, and mother of nine children, had for five years suffered from swelling and ulceration of the right leg. She could not recall having either "white leg" or varicose veins. The ulcer, starting from an abrasion, had gradually grown to an immense size. The area was 67 square inches, and the girth of the leg 15 inches at the upper margin of the ulcer (*Plate, Fig. 1*).

Her suffering had been terrible, and she appeared worn out with constant pain and sleeplessness. The exhaustion showed itself in her face, giving her what I have called the "ulcer facies" (Fig. 4). The discharge from the ulcer was most profuse, and this constant albuminous drain had led to a profound secondary anaemia, with a haemoglobin percentage

of 35. The Wassermann reaction was negative. The ulcer showed an almost pure culture of *B. pyocyaneus*, and the discharge from the ulcer had no inhibitory effect upon the growth of the organisms. A test with milk showed the presence of trypsin in the discharge. The margins of the ulcer were stony hard, and there was only a narrow strip of skin connecting the skin of the foot with that of the upper part of the leg.

Without any delay, although the ulcer was so foul, it was bound tightly with adhesive plaster. Strips were laid first as shown in Figure 5, to stop the spiral bandage cutting furrows

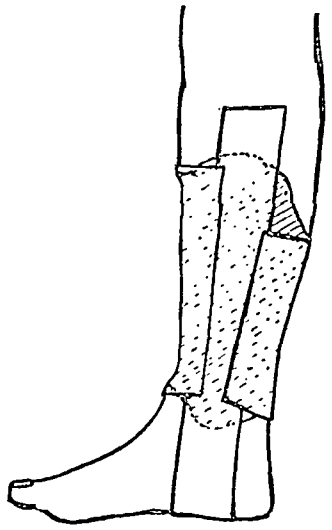

Fig. 5.—Longitudinal strips put on before the spiral compressing bandage: 1. To prevent the cutting of grooves in the oedematous leg. 2. To prevent the bandage from slipping out of position on the surface of the ulcer which is too moist for the bandage to adhere. This precaution is not necessary when the ulcer is small or the oedema moderate.

in the oedema. A great pressure was used, and, as usual, the patient complained that "she could never stand it." At weekly intervals the bandage was removed (by the patient) and renewed; on four occasions skin was removed from the forearm and slipped under the granulations, once by darning, and three times by implantation.

Although this ulcer was so large, it continued to heal steadily and smoothly, and at the end of thirteen weeks was com-

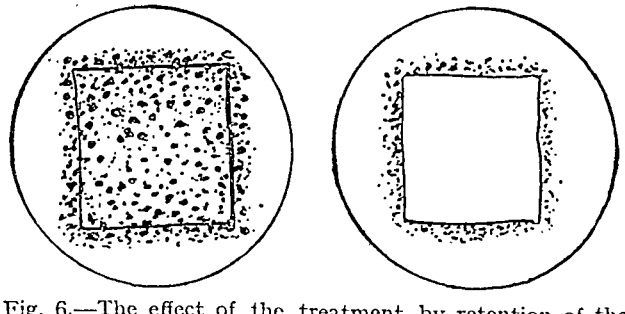

Fig. 6.—The effect of the treatment by retention of the discharge and compression of the whole leg upon the bactericidal power of the pus. On the left, before treatment an abundant growth occurs both in the dried discharge round as well as in the moist discharge *under* the cover slip. On the right, after two weeks of treatment the moist discharge under the slip inhibits the bacterial growth.

pletely epithelialized after the application of ten bandages, and the girth of the leg was reduced to twelve inches where it had been fifteen inches (Plate, Fig. 2). With the healing of the ulcer, the discharge diminished, and from the start of the treatment the pain ceased, sleep came, and the lines of pain disappeared from the face; the weight increased by 28 pounds, and the haemoglobin rose to 85 per cent. (Dare).

Sir Almroth Wright investigated the discharge under the adhesive dressing, and found that it now inhibited the growth of the organisms and contained no trypsin. Fig. 6 shows diagrammatically the effect of culture on the discharge. The culture was made by placing a drop of the discharge on a cover slip, and placing it on the surface of medium in a Petri dish. The discharge which *oozes out* at the edges inspissates, and so its contained leucocytes die, whereas the discharge under the slide remains moist and its leucocytes active. At the edges one has necro-pyo-culture, and under the slide bio-pyo-culture.

The remarkable point about this case is that at no time were any varicose veins discovered, and there was no definite history of femoral thrombosis. One can only infer that some change occurred in the venous return of the leg, resulting from the repeated pregnancies, and a vicious circle was inaugurated, resulting in the advanced ulceration.

The value of the term "gravitational ulcer" is illustrated by a case of this kind. A point of interest is that this patient had refused many requests for amputation.

CONCLUSION

Loss of circulatory equilibrium in the leg inaugurates a train of pathological changes in a certain well-defined area, where the effect of gravity is at its maximum in the unsupported lower extremity. These changes are numerous, and can be summarized as follows:

Oedema.—(*a*) Occurring towards the end of the day and pitting on pressure; (*b*) permanent oedema which still pits on pressure; (*c*) elastic oedema when the skin is tightly stretched, and there is no pitting on pressure; (*d*) indurated oedema which is the final stage, and is frequently associated with ulcer.

Changes in the Blood.—(*a*) Increase of lactic acid and carbon dioxide; (*b*) decrease in oxygen content.

Changes in the Skin Structures.—(*a*) Loss of hair on the leg; (*b*) drying up of secretions of sweat and sebaceous glands.

Inflammatory Changes in the Skin.—(*a*) Eczema of dry, scaly, or exudative type; (*b*) septic blisters of skin; (*c*) pruritus; (*d*) dermatitis artefacta from the scratching; (*e*) erysipelas.

Ulceration involving (*a*) skin; (*b*) subcutaneous tissue; (*c*) tendons and muscle very rarely; (*d*) bone, even more rarely.

Changes in Subcutaneous Tissues.—(*a*) Inflammation in the neighbourhood of the veins—periphlebitis—which is very common, and often miscalled phlebitis; (*b*) fibrosis, which is always present in ulcer cases; (*c*) suppuration; (*d*) ossification, which may take place in the bed of the ulcer, but more usually throughout the whole of the devitalized area in patches; (*e*) calcification.

Gangrene in the ulcer-bearing area when arterial supervenes upon venous disease.

Changes in the Muscles.—(*a*) Brown degeneration and atrophy; (*b*) ossification and calcification; (*c*) contractures from fibrosis.

Changes in the Bones.—(*a*) Periostitis, which more commonly affects the fibula for some unknown reason; (*b*) osteitis, with rarefaction and cystic areas in the bone.

Changes in Joints.—(*a*) Atrophic arthritis; (*b*) osteo-arthritis; (*c*) ankylosis.

Changes in the Veins.—(*a*) Rupture; (*b*) phlebitis, which is occasionally suppurative.

Changes in Fascia.—Usually ossification of interosseous membrane and other intermuscular septa.

Changes Secondary to Ulceration.—(*a*) Malignant (Marjolin's) disease, which seems to be much more common in men; (*b*) tetanus; (*c*) deformities of the foot and knee, resulting from faulty posture in walking in an endeavour to relieve pain, producing pes cavus, equinus, valgus or varus, alone or combined. This deformity is at first spastic, and disappears when the pain goes, but later on the muscles become permanently contracted. I have

twice done tendon lengthening operations for this type of deformity Deformity resulting from fibrosis of the ulcer bed generally produces talipes equinus and calcaneus, (d) mental changes, chiefly melancholia, neurasthenia, and lebetude

COMMENTARY

This is a very formidable list of complications to which varities can still be added They all result from loss of balance between arterial and venous systems of the leg This balance can be restored in two ways—by lying down and by reinforcing the skin with an elastic support In the cases due to varicose veins a great improvement can be made by obliterating, and in bad cases also ligating, the varices, so that 75 per cent of ulcer cases can be cured and remain cured, without any support but the elasticity of the patient's own skin

Ulcers of the leg will always be with us till we find a way of preventing femoral thrombosis after operations, fractures and childbirth, but they will diminish in number because of the simplicity of the injection treatment for early varicose veins By this method of treatment we have a certain way of curing all gravitational ulcers The treatment of small ulcers, up to 4 square inches is a very simple matter, quickly accomplished with a minimum of trouble These ulcers can be cured by other methods I admit, but generally at the expense of much trouble and time to patient and surgeon The larger ulcers are generally acknowledged to be incurable but they can be readily cleared up by this method, even when of the gigantic dimensions of 180 square inches (1¼ square feet!), the largest ulcer I have yet treated since I have kept statistics I have now 525 cases of cured ulcer of a total area of a little over 25 square feet

One of the most wonderful things in nature is surely to see the ulcer which started a quarter to half a century ago (my longest case is fifty four years) begin to throw up its granulations flatten out its margins pull in its edges and epithelialize in the way described so well by the "Father of Surgery"—John Hunter—many years ago

A CASE OF ACHALASIA OF THE CARDIA

BY

H B BUTLER, F R C S Ed

SURGEON ROYAL SURREY COUNTY HOSPITAL GUILDFORD

(*With Special Plate*)

The following is the history of a male B K, aged 35, who was sent to the *x* ray department of the Royal Surrey County Hospital with a probable diagnosis of pyloric obstruction

There was a history of difficulty in "swallowing" for the past two years much worse during the last four months He had lost about a stone during the latter period but though rather emaciated his physical condition was fairly good He was of the opinion that all his food returned after having been retained for some hours it gradually worked up but he did not actually vomit He got a feeling of tightness and great discomfort in the chest until the food was regurgitated He had been given a barium meal at home six hours before being seen at hospital and when he was examined on the screen it was seen that this meal was still in the greatly distended oesophagus none being seen in the stomach or else where The obstruction was at the cardia

The oesophagus was evacuated and then a soft mercury tube was passed into the stomach without any obstruction being encountered Immediately after the passage of the tube he was given half a pint of beaten egg and milk which he swallowed with ease and evident pleasure saying that it was the first food he had felt entering his stomach for months He was admitted to hospital to be taught to pass the tube himself which he soon accomplished, passing it before every feed and he was discharged in about a week able to take all soft food and doing well

On June 14th 1929 he came again and complained of difficulty in swallowing but as the tube was seen to pass easily into his stomach he was told to persevere (see Plate, Fig 1) On July 27th he was readmitted his condition then being nearly as bad as when first seen Fig 2 shows an immediate meal distending the oesophagus (July 27th) Fig 3 taken on July 31st shows a mercury tube which he was able himself to pass into his stomach Fig 4 shows a bread and milk barium meal the consistency of cream taken immediately after the successful passage of the tube and demonstrates the fact that the achalasia was immediately present even directly after dilatation with a large sized tube

No obvious cause for the condition could be discovered and the patient begged for an operation and be done with it I had had no experience of dilatation with an inflatable bag and felt that operation offered the best chance of success Operation was performed on August 1st No cancer or ulcer of the stomach or duodenum was found nor any lesion of the gall bladder A transverse incision in the anterior wall allowed three fingers to be introduced into the stomach but to my surprise I had great difficulty in locating the cardia (In this connexion I was afterwards interested to read in a paper published by the Mayo Clinic The silk thread is just as valuable a guide to manual dilatation from below as it is to dilatation from above by means of the hydrostatic dilator[1]) When the cardia was found one finger was introduced then a second and then a third before there was any sensation that further dilatation would be dangerous There was no palpable hypertrophy The stomach and the abdominal wound were then closed The patient made an uninterrupted recovery and left the hospital within three weeks

As I had no report about this patient I wrote to him and received a reply dated April 17th 1931 I am pleased to inform you that I am still going strong and can eat anything that comes along from beef steaks eggs and bacon to meat pies in fact I have not found anything yet that I cannot swallow Twelve months ago I secured light employment and have continued to work regular ever since and have had no need to visit my doctor

There seems to be little doubt that, in the large majority of cases a cure can be obtained by forced dilatation In approximately 700 cases at the Mayo Clinic dilatation has been carried out readily and satisfactorily from above, by means of the bag, only three requiring dilatation from below[1] On the other hand, Hurst[2] finds that the far simpler treatment, by means of the mercury tube, is effective in the majority of cases, and only reports one case in which no lasting improvement occurred In this case forcible dilatation by the bag proved equally unsuccessful, and the patient was operated on by Rowlands, who divided the cardiac sphincter in exactly the same way as the pyloric sphincter is divided in Rammstedt's operation for the hypertrophic pyloric stenosis of infants, the operation curing the condition, which had been present for seven years If treatment is undertaken by means of a bag, it would obviously be an advantage if the bag were opaque to *x* rays so that dilatation could be carried out under direct observation and its correct position verified

A M J Wright in the *Medical Annual* 1930 extracting from H P Mosher's Semon Lecture says The author employs dilatation with an inflatable bag under manometer control the bag having barium implanted in four strips in its wall so that the dilatation can be carried out under direct observation with the *x* ray screen

AN INVESTIGATION OF DIPHTHERIA CARRIERS

BY

JAMES GRANT, M.B., CH.B., D.P.H.GLAS.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER, BURTON-ON-TRENT

Routine swabbing of young domestic contacts of diphtheria cases has been followed in this borough for many years. As the disease remained of sporadic incidence until 1928, the few contact carriers were easily dealt with by isolation in the borough isolation hospital. In 1928, however, not only did diphtheria increase in prevalence, but so also did the ratio of carriers, these conditions enduring to the latter end of 1930, when there was simultaneous prevalence of both scarlet fever and diphtheria. The following table shows the number of cases of diphtheria notified from 1927 to April, 1931, and the number of contacts dealt with.

	Diphtheria Cases Notified	Contacts Dealt With	Contacts with Positive Swabs
1927	63	72	3
1928	173	167	19
1929	230	275	29
1930	295	212	23
1931 (to April 1st)	22	38	2

In addition, nine contacts were found to be suffering from clinical diphtheria of the fauces at the time of inspection and swabbing, and many other cases of multiple infection in the family were dealt with by the practitioner in attendance. With the progress of the epidemic, one became familiar with the appearance of the nose likely to harbour diphtheria bacilli, and inspections of school children in infected classes yielded many other supposed carriers. The children deemed to be carriers were supervised by their own doctors or at the school clinic. Some 53 children, made up of 33 contacts (22 throat and 11 nasal carriers), 19 nasal carriers found in school, and 1 contact with diphtheria bacilli in both throat and nose, were treated at the school clinic. All of these at first yielded practically pure cultures of Klebs-Loeffler bacilli, and were excluded from school under daily supervision until negative swabs were obtained. I have little doubt that nearly all these carriers harboured virulent bacilli, as they were intimate contacts of diphtheria cases.

TREATMENT OF CARRIERS AND RESULTS

Treatment of these children did not impose any arduous duties on the school staff. Throat carriers had their tonsils painted daily with tinct. iodi mitis, and nasal carriers had the anterior nares swabbed with hydrogen peroxide to remove crusts, white precipitate ointment then being applied to the site. Wooden applicators were extremely useful in performing this toilet. These measures were as effective as any of the various antiseptics tried simultaneously in dealing with convalescent carriers in the borough hospital. Antitoxin had no effect on the carrier condition in my experience, although used in three cases. The conditions observed locally were interesting. Throat carriers seldom had normal fauces, and the duration of infectivity varied directly with the unhealthy state of the tonsillar tissue. Nasal carriers practically always had a sore or small excoriation of one or both nostrils, frequently with an acrid nasal discharge; in one instance there was a septic enlargement of the glands in the neck. They often yielded positive swabs long after the local condition became normal. In most instances positive swabs were obtained for about three weeks only, but a few continued to harbour diphtheria bacilli for periods of two to three months. Three chronic throat carriers (not included above) of the convalescent type came under notice, and here tonsillectomy effected a cure.

At the school clinic isolation of the carriers was maintained as far as possible by giving them a waiting room apart from the other children. Only two fresh cases of diphtheria occurred in association with these carriers after detection. One was a domestic infection of faucial diphtheria derived from a nasal carrier detected in school. The other was in a boy who attended the school clinic for three days with a minor ailment, and contracted diphtheria on the fourth day. Virulence tests were performed only in ten instances, as laboratory animals were not kept in the small laboratory of the public health department. Such tests were carried out in a public health laboratory elsewhere, and, where isolation of the bacillus was possible, one never had a negative result. This isolation was facilitated by sending primary cultures inoculated within an hour of taking the swab and incubated overnight. There was evidence, in two cases where this was not done, that the bacilli in the swab failed to survive a postal journey.

REMARKS ON IMMUNITY

There seem to be two kinds of possible immunity to diphtheria. One might be styled anti-bacterial immunity and the other antitoxic immunity. The latter by no means confers the first, and the first seems to me to depend on phagocytosis, and to be evanescent. Antitoxin proved of little help to the carrier, nor did an attack of diphtheria a year or two before protect against the carrier state—as observed in two instances in this series. Further, it may be stated that antitoxin given prophylactically does not give passive immunity to the carrier state. Despite every precaution, on three occasions during the period of the epidemic, the scarlet fever wards, when filled to capacity, were infected by cases of diphtheria complicating scarlet fever. Passive immunity methods were thereupon freely used, and certainly prevented the appearance of clinical diphtheria. Yet the carrier condition spread through the throats and noses of the immunized children without any symptoms beyond a few "sore noses." Two of these cases proved very persistent carriers of virulent diphtheria bacilli, and yielded pure cultures for three months. Clinical diphtheria occurred among other members of the household in one or two instances where these carriers were discharged from the scarlet fever ward before detection.

CONCLUSION

Many scoff at the procedure of swabbing diphtheria contacts. The discovery of clinical diphtheria among them is sufficient warranty for the continuance of the practice, however cumbersome it may be. A further merit is that many valuable days of school attendance are saved by allowing contacts with negative swabs to return to school at once. Attendance at a centre such as the school clinic solves the problem of what to do with the carriers, and maintains touch with infectious individuals and their families. I would suggest, however, that a routine virulence test be carried out on diphtheria bacilli persisting longer than four weeks in contact carriers. Finally, it is evident that further research is required into the immunology of the diphtheria bacillus as opposed to its toxin.

I am indebted to Dr. J. M. Cowie, medical officer of health, for permission to publish these observations.

EPIDEMIC MENINGITIS MINOR

BY

J. V. C. BRAITHWAITE, M.D., M.R.C.P.LOND.

PHYSICIAN AND PHYSICIAN IN CHARGE OF THE CHILDREN'S DEPARTMENT, LEICESTER ROYAL INFIRMARY

AND

W. MITCHELL INNES, M.B., CH.B.ED.

HOUSE PHYSICIAN, LEICESTER ROYAL INFIRMARY

During the period from February 21st to April 8th of this year thirteen children suffering from symptoms of meningitis were admitted into the Children's Hospital of the Leicester Royal Infirmary. They presented a clinical picture similar to that described by Quincke[1] in 1893 under the name "serous meningitis," although the affection from which they suffered differed from this disease in several important particulars.

Sporadic cases of meningitis of the Quincke type are not uncommon. During the four years from 1927 to 1930, 35 were admitted into the Leicester Royal Infirmary. The age of the patients varied from 8 months to 64 years, although children were mostly affected, only two being over the age of 13 years. There were 24 males and 11 females; 4 died apparently from the condition itself, 13 from other concomitant diseases, chiefly broncho-pneumonia. But although this sporadic type is well recognized, there is no record of the affection assuming an epidemic character in this country. Recently Schneider[2] has reported an epidemic of serous meningitis, and he refers to several similar outbreaks in Germany. But here again the present series of cases do not present features entirely similar to those of the German epidemics, or to those admitted into this hospital during the previous four years.

SYMPTOMS AND PHYSICAL SIGNS

Eight of the cases now under consideration were secondary to broncho-pneumonia, usually of a mild type, the other five being apparently primary. The onset was sudden in seven, insidious in six. Vomiting, headache, and drowsiness were the most constant symptoms. Vomiting occurred in seven cases. Headache and drowsiness were complained of six times each, as five of the patients were under the age of 1 year, and abnormal crying was a symptom of these. Headache is probably a constant complaint. Convulsions were reported in five cases. Diarrhoea was present in five patients, constipation in three. Two were delirious. Increased thirst was noticed twice. There was grinding of the teeth in one case. One patient complained of abdominal pain.

Nuchal rigidity was present in all thirteen patients, while eleven of them exhibited a positive Kernig sign. In all but one case the temperature was raised to a varying degree, in three cases it reached 104° F. There was bulging of the fontanelle when this was patent. Strabismus was strikingly absent. In the older children in whom the fundi oculorum were examined there was no papilloedema. In no case was there any evidence of disease of the middle ear.

CLINICAL COURSE

All the patients but one recovered. In the fatal case the patient recovered from the meningeal symptoms, but he had broncho-pneumonia and contracted diphtheria, he was apparently doing well when there was a recurrence of the broncho-pneumonia, from which he died.

In this and one other case lumbar puncture was not performed—the one was transferred to the isolation hospital and in the other the symptoms disappeared spontaneously within twenty-four hours of admission. The primary cases cleared up very shortly after lumbar puncture, usually within twenty-four hours. As a rule there was a history of illness lasting from two days to one week before admission. In the secondary cases, the meningeal signs cleared up on lumbar puncture, while the broncho-pneumonia ran a short course of seven to sixteen days. In one case, however, the broncho-pneumonia persisted for six weeks.

THE CEREBRO-SPINAL FLUID

Cerebro-spinal fluid was obtained from eleven patients. In all cases it was under increased pressure, clear, and sterile. It did not form a coagulum on standing.

The protein was usually slightly increased. The average amount was 0·057 per cent.; three specimens had only 0·02 per cent. while one specimen showed a greatly increased protein content—0·2 per cent.

The cells in ten cases were under 5 per c.mm. In one case—that with the very high protein—they were increased to 40 per c.mm. and these were mostly lymphocytes.

The chlorides were estimated in nine cases and the results were always within normal limits. The average was 712 mg. per 100 c.cm., the limits being 690 and 750 mg. per 100 c.cm.

Sugar was always present. The actual amount was only estimated in one case, when it was found to be 0·062 per cent.

TREATMENT

The only treatment given was lumbar or cisternal puncture. This resulted in a complete disappearance of all meningeal symptoms, usually after one operation. In two cases two punctures were necessary before resolution occurred.

ETIOLOGY

As has already been stated, five cases were primary and eight secondary to broncho-pneumonia. But while these last are termed 'secondary' the meningeal symptoms all occurred at the onset of the disease, so that the two affections appeared concomitantly. The patients were usually sent in by outside doctors about the fourth or fifth day from the onset with the diagnosis broncho-pneumonia and meningitis.

Sex.—There was a marked preponderance of males in this small series—ten males to three females. With such a small number of cases this may or may not be of significance. It will be remembered that in the sporadic cases that have occurred in Leicester in the four previous years there were twenty-four males to eleven females.

Age.—The two youngest of our patients were 9 weeks old, the eldest 6 years. The ages of the other patients were 10 weeks, 6 months, 10 months, 14 months, 15 months (2), 3 years, 4 years (2), and 5 years.

Concomitant Epidemics.—The cases all occurred during or near March, 1931. During this time two mild epidemics were prevalent locally—cerebro-spinal meningitis and influenza. In no case was there a history of one of our patients having been exposed to these infections knowingly. No case had been admitted in 1931 before February 21st, and up to the time of writing (June) no case has been admitted since April 8th.

DISCUSSION

Undoubtedly this series of cases bears a strong resemblance to Quincke's serous meningitis. In his original description that author groups the cases as follows:

I. Those with acute onset
   - (*a*) With acute course
   - (*b*) With chronic course

II. Chronic cases
   - (*a*) With chronic progressive course
   - (*b*) Chronic cases with acute exacerbations

The cases described by us resemble most clearly those included in I (*a*)—cases with acute onset and acute course. This agrees well with Quincke's observation that

the younger the age at onset the more likely is the condition to be acute, as all our cases occurred in early childhood Indeed, this constitutes one of the most striking points about this epidemic. Quincke stated that serous meningitis is mainly a disease of young adults, but that cases do occur in childhood. Of his six acute cases reported, three patients were 20 or more, one was 14, one $3\frac{1}{2}$, and one $1\frac{3}{4}$ years old. Another striking point of difference between the cases now under discussion and those described by Quincke is the shortness of the course. In our cases all meningeal symptoms cleared up in a few days after lumbar puncture Quincke's acute cases lasted from four weeks to five months Fever was marked in all but one of our patients, whereas it was absent or slight in Quincke's. Only one of the latter's—the youngest—suffered from broncho-pneumonia, whereas it was present in the majority of our patients.

Since Quincke's time the condition has been fairly well recognized, but little new has been added to our knowledge A good modern description of the disease (now translated into English) is given by Ibraham.[3] The most important differences between the affection as described by him and the present series of cases are: (1) the frequency of otitis media as a point of origin; (2) the common occurrence of fatal cases (Ibraham states that the more acute the onset the greater the mortality); (3) the formation of a fibrin clot in the fluid obtained by lumbar puncture, (4) the occasional growth of micro-organisms from the cerebro-spinal fluid (*B influenzae*, *B coli*, pneumococci, streptococci, or staphylococci), (5) the occurrence of tetany as a complication—of evil prognostic import.

The most recent account is that given by Schneider referred to above The affection appears to be more or less endemic in Central Europe, with mild epidemic outbreaks. Although in previous German epidemics children were mostly affected, the youngest of Schneider's patients was 14 years old, the majority were middle-aged adults, and there was no marked preponderance of either sex. The cerebro-spinal fluid was sometimes opalescent, the cell count and protein both being increased. The author believes the disease to be an abortive form of cerebro-spinal meningitis.

It is interesting to note in this connexion that there was a mild epidemic of cerebro-spinal fever at the same time as the occurrence of our cases. However, in our opinion, the very frequent coincident broncho-pneumonia points rather to an influenzal infection being the cause—especially when it is remembered that there was also an influenza epidemic at the time. Lafora[4] in 1922 expressed the opinion that influenza was a frequent cause of serous meningitis, and he reported a chronic case following influenza in a woman of 35, who was cured by repeated lumbar puncture. Indeed, it does not appear unreasonable to suppose that this form of meningitis may result from mild infections of various natures, influenza perhaps being the commonest; and we suggest that the name "meningitis minor" be applied to them to differentiate them from the infinitely graver suppurative or tuberculous forms. The name "serous meningitis," while it distinguishes them from the former, does not denote the profound way in which these mild cases differ from tuberculous meningitis Dr C. P. Symonds, in conversation with one of us (J. V. C. B), pointed out the inaccuracy of the term "serous meningitis."

SUMMARY

1 Thirteen patients with symptoms of meningitis were admitted into hospital in six and a half weeks during the early spring of this year.

2 Eight of the thirteen had coincident broncho-pneumonia.

3. All the patients were young children, ten were boys.

4. The cerebro-spinal fluid was under pressure, clear, and sterile. The protein tended to be increased slightly, but usually there was no other abnormality

5. Lumbar or cisternal puncture caused rapid and complete disappearance of the symptoms.

6 The condition may be an abortive form either of influenzal or cerebro-spinal meningitis. In the present cases it was probably the former.

7. The disease, while resembling that described by Quincke as serous meningitis, shows several important differences, particularly in its benign course It is suggested that the name "meningitis minor" is preferable.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

POISONING FROM MOTOR CAR EXHAUST FUMES

In the last year two cases of poisoning from exhaust fumes have been observed. The cases were so very similar that a description of one only is thought necessary

A removal agent came to see me one day in December He had seen two doctors in a month, and neither could help him I was equally stumped by his symptoms, but hit upon the diagnosis by chance.

Since 1919, when he left the Army, in which he was a transport officer, this man had been employed by a firm of removal contractors, and worked twelve to fifteen hours a day He had never had a holiday His job is to go from Leeds to any town in England to arrange a removal This he does by car.

Till the early part of last year he had no complaint and enjoyed his work In February he found himself much more easily tired than usual. His eyesight worried him a little He gave the following example, which shows at the same time what a strenuous day's work he was in the habit of doing One day he went to the office at 9 a.m. read his letters, and dictated replies At 11 o'clock he motored to Manchester, arranged for a removal, and motored back, arriving at 5 p.m After two hours in the office he had tea, a meal, and set out by road for Newcastle-on-Tyne He was sleepy, and his eyes were heavy as he drove—"a most unusual state of affairs"—but he arrived there at 11 P.M. completed his business, and set off for home In the next few hours he noticed that the lights of approaching traffic seemed to flicker and flash A little later he caught himself on the verge of falling asleep—a feeling he had never experienced before. He wisely pulled up, and slept for half an hour He started again, but had great difficulty in driving because he could not place lights correctly on the road He could see the light of a house, but it would be so unsteady that he could not determine on which side of the road the house was. Several times he stopped, overpowered with sleep, but eventually he reached home A few hours in bed restored him to a feeling of comparative freshness, but when he got into the car the feeling of helplessness overcame him The climax arrived one day when he stopped at a robot light. For minutes he tried to decide when the light was green and when red He could see the change in colour, but could not remember which colour stood for safety and which for danger. He thereupon hired a chauffeur, but he got worse He was under medical treatment, and was having more than usual.

When I saw him he had a pulse rate of 54, a blood pressure of 108/92. His tendon jerks were scarcely perceptible. His eye light reflex was almost absent, the pupil being small. There was no colour blindness. His speech was staccato and rapid, the words falling over one another. His hair was falling rapidly. He sweated easily. His tongue was dirty, but he had no symptoms of digestive trouble. He was very nervous, and could not sit still a moment. There was no apparent loss in weight.

After three days in bed, on thyroid and injections of Trasse's neurosthenic ampoules (he had gone to bed with a diagnosis of neurasthenia due to overwork), he was much better. He insisted on returning to work on the fourth day. On the fifth day his symptoms began to recur. I happened to meet him in the street, and in a conversation about his car he mentioned how long he had had it. This period coincided with the length of time his symptoms had been observed. On inquiry, it was discovered that fumes from the engine were noticed in the car on long runs, and that he always had the windows shut, or nearly so. He was advised to have the floor boards sealed against gases and a new exhaust washer put in place. His symptoms disappeared in about ten days, and he has had no recurrence.

The similarity of the second case was so marked that it seems worth while publishing these symptoms in the hope that they may prove of help to others. The other man was a motor salesman. The inability to focus and place lights at night, the fatigue, and the inability to recognize colours were described in the same order. His car had leaking floor boards, and was of the same make as the first car mentioned. The new models of this type have improved floor boards and improved design for removing exhaust gases.

Leeds R. A. MURRAY SCOTT, M.A., M.B., B.Chir.

DEATH FOLLOWING SODIUM TETRA-IODOPHENOLPHTHALEIN

Sodium tetraiodophenolphthalein for cholecystography only occasionally gives rise to untoward symptoms, and rarely has fatal results, provided its contraindications are observed. Among these is heart disease, but the difficulty is, with the means ordinarily at the physician's disposal, to detect unsuspected myocardial degeneration such as fatty infiltration.

I was asked, on August 11th, by the East Middlesex coroner (Dr. George Cohen) to do a post-mortem examination—soon after death—in the case of a woman, aged 60, who collapsed and died after the fifth of a series of capsules, each of 0.5 gram, of sodium tetraiodophenolphthalein, taken at half-hourly intervals for cholecystography. Externally the whole surface of the body (moderately well nourished) had an icteric tinge, but especially the conjunctivae. Internally, there were evidences of fairly grave anaemia; greenish discoloration of the liver, chronic cholecystitis, no bile; six stones, the colour, size, and appearance of peppercorns, in the gall-bladder, one in the cystic duct, and two in the common duct, and chronic pancreatitis.

On lifting the heart, without undue force, from the pericardium, the dissector's thumb penetrated the wall, so advanced was its degeneration: a fatty infiltration involving even the chordae tendineae. Kidneys, pale, showed fairly advanced interstitial changes. The stomach (which had been washed out) was undamaged, but the first six feet of small intestine showed a well-defined hyperaemia of varying degrees of severity, and its mucosa was smeared with the drug. The hyperaemia is of interest in view of the griping complained of in the severe reactions occasionally seen and yielding to adrenaline.

Reviews

BRIGHT'S DISEASE

The beautifully illustrated monograph by Professor THOMAS ADDIS and Dr. JEAN OLIVER on *The Renal Lesion in Bright's Disease*[1] is the result of ten years' work, and, like Bright's original account in 1827 and Volhard and Fahr's volume in 1914, it is designed to correlate the clinical manifestations with the morbid changes in the kidneys. The attractions of functional tests of renal efficiency have recently tended to concentrate attention somewhat too exclusively in one direction, and Professor Addis out of his full clinical experience submits this attitude to a critical and penetrating analysis. The bearing of efficiency tests on prognosis is disappointing, for the same abnormalities of function are present in transient lesions as in those that are lasting, progressive, and fatal; the tests do not indicate the nature of the morbid change which has affected the functioning tissue, and it is the nature of the lesion, not its extent, that determines the patient's fate. The warning is thrown out that the clinical tests now in vogue have no more lasting value than the quite provisional hypotheses on which they are based, and that the hopes entertained as to their value "were from the first unwarranted because our conceptions as to the physiology of the kidney are quite naturally as childish and incomplete as is our knowledge of its structure." But it must not be supposed that Professor Addis neglects in the least their use and any information that can be obtained from laboratory investigation, for the clinical notes on seventy-two patients with various forms of Bright's disease, on whom necropsies were eventually obtained, show that the blood urea concentration, the volume of urine, rate of protein excretion, specific gravity, and a full examination of the sediment were regularly investigated. Their limitations, however, are insisted on, thus the diagnosis of renal disease by urinary examination depends on a quantitative, not on a qualitative, basis. Formerly it was generally supposed that casts and red blood corpuscles were evidence of definite morbid change in the kidneys; but examination of the urine of seventy-four healthy medical students gave the quite unexpected information that the twelve hours' urine contained on an average 1,040 casts, 65,750 red blood cells, 322,500 white cells and epithelial cells, and protein between 10 and 30 mg. A protein excretion of more than 30 mg. and a rate of cast excretion above 5,000 per twelve hours were regarded as pathological.

The clinical and pathological records of the seventy-two cases, each with plates of the microscopical appearances, are contributed jointly by the two authors, who otherwise are separately responsible for the remaining ten chapters on the clinical and pathological aspects of the subject. The authors write from their own points of view, but they reach the same conclusions. The confusing nomenclature of renal disease has much to answer for; instead of the use of the term "nephritis," which connotes inflammation of some sort, the *non-committal* eponymic Bright's disease is employed, and is divided into three main groups—haemorrhagic, *degenerative*, and arterio-sclerotic. Every student of Bright's disease is tempted to construct a classification, thus Miss Dorothy S. Russell suggested a new one in 1929. There is a great virtue in simplicity, and in this and other respects Addis and Oliver's groups closely resemble those of Volhard and Fahr, whose nephrosis corresponds to the degenerative

[1] *The Renal Lesion in Bright's Disease*. By Thomas Addis and Jean Oliver. New York: P. B. Hoeber, Inc. 1931. (Pp. xi + 628, 170 plates, 2 in colour, 21 figures, 1 folding table. 16 dollars.)

Bright's disease of the American authors. This is a heterogeneous category, and includes patients with unrelated diseases united in the occurrence of a renal lesion distinct from haemorrhagic and arterio-sclerotic Bright's disease. The two last forms are irreversible, whereas the degenerative is reversible; thus in the late toxaemia of pregnancy there is clinical evidence of a most intense degeneration; but within twenty-four hours of delivery everything has quieted down, and in a few weeks there may not be any trace of a renal lesion. This feature is a clinical justification for the recognition of the group. On the use of the words "nephritis" and "nephrosis" Professor Oliver remarks that they are evidently "all things to all men," "and if the ablest have used them to apply to the same thing with meanings exactly the converse, this fact alone would seem to prejudice their usefulness if any scientific accuracy is desired in nomenclature."

This work is not on the lines of a dogmatic textbook, but is the philosophic critique of a difficult subject based on a laborious research conducted and correlated on clinical and pathological lines.

ABDOMINAL PAIN

We believe that few practitioners who commence Mr. JOHN MORLEY'S modest volume, entitled *Abdominal Pain*,[2] will put it aside until they have completed the final page. It is eminently readable. Its argument is based on personal experience and careful thought. And though a controversial contribution, it never fails in courtesy or in generosity. Mr. Morley starts from the experience that the current doctrines of referred pain, and the clinical conclusions founded on them, do not in fact work; the student is confused by them and the practitioner discards them. Hence the claim for a review of the situation. It is not inappropriate that this review should be undertaken by a teacher in the Manchester School, for the theory so energetically advocated in recent years by the late Sir James Mackenzie took origin in the work of Dr. James Ross, whose classical textbook on *Diseases of the Nervous System*, published in 1881, carried his fame far beyond the western city where he practised. While Mr. Morley holds in the greatest respect the personalities and work of his predecessors, he is quite firm in his contention that the theory of referred pain for which they are responsible cannot be sustained, and he is not less confident in his presentation of an alternative view. Briefly, his claim is that the deep and superficial tenderness and muscular rigidity of the abdominal wall, so commonly observed in association with inflammatory disorders in the abdomen, are not reflex phenomena originated by stimulation of the afferent autonomic nerves of the viscera, but that, on the contrary, the starting-point of the reflex activity of which they are the expression is in the highly sensitive cerebro-spinal nerves of the parietal peritoneum. His thesis is tested by applying it to pain as this results from all forms of organic disease within the abdomen, and the examination is not less candid than it is thorough. Particular attention may be directed to the chapters dealing with shoulder-tip pain and with pain in appendicitis, and to the full clinical experience on which the argument is based. Even for those to whom doctrine and theory make little appeal the practical teaching of the book relative to the diagnostic significance of pain in the abdomen makes Mr. Morley's study a valuable contribution. And it is not without interest to note that surgery, with its ability to study the "pathology of the living," may offer some significant experiences both to the academic physiologist and to the clinical student of the nervous system. Alike in its theoretical discussion and in its bedside teaching, Mr. Morley's book will, we are sure, commend itself to many readers.

TREATMENT OF EPILEPSY BY KETOSIS

The treatment of epilepsy by means of ketosis induced by a diet rich in fat has now been tried for a number of years. The time is therefore ripe for a critical review of the results obtained by this method of treatment. Dr. FRITZ B. TALBOT'S book, *Treatment of Epilepsy*,[3] is mainly concerned with the use of a ketogenic diet. He gives a detailed account of the physiological principles underlying the production of ketosis and of the methods of estimating the dietary requirements of patients. A number of specimen diets are given. Dr. Talbot's book is, however, somewhat disappointing. One-third is devoted to a rather sketchy review of etiology and symptomatology, which compares unfavourably with the recent consideration of these aspects of the subject by Cobb and Lennox. Though the book is called *Treatment of Epilepsy*, very little space is devoted to treatment by drugs. In considering the results of treatment by ketogenic diet Dr. Talbot is able to quote 240 cases, of which only twenty were treated by himself. It appears that in children complete relief was obtained in from 25 to 50 per cent. of cases, and improvement in from 23 to 45 per cent. Roughly speaking, one-third were freed from fits, one-third were improved but not completely relieved, and one-third were unaffected. It is generally agreed that adults respond to a ketogenic diet less satisfactorily than children.

Dr. Talbot discusses briefly the treatment of epilepsy by dehydration. His own limited experience of this method has not been encouraging. There are several serious verbal errors. On page 160 "ketogenic substances, mainly carbohydrate" is clearly incorrect. Elsewhere the author does not always make his meaning clear.

Anyone who wishes to treat an epileptic patient by means of the ketogenic diet will find full instructions in Dr. Talbot's book. Though this method is valuable in some cases and certainly justifiable, the value of dehydration is at present unsettled, and the patient whose intake of water is reduced to 6 oz. a day may perhaps be pardoned for thinking that the cure is worse than the disease.

PRIMITIVE PSYCHOLOGY

An adherent of the Zürich School of Psychology, Mr. C. R. ALDRICH attempts in *The Primitive Mind and Modern Civilization*[4] to harmonize the concept of the racial unconscious, which that school has adopted as the main article of its creed, with the findings of anthropology. His conclusion is that the race progresses from the unconscious towards consciousness by three stages. The first is an "unconscious bio-morality," earlier defined as "the collective unconscious morality inherent in the laws of life"; the second is a period of savagery, in which the group represses egotistic tendencies by forcibly imposing a conventional morality; the third—not yet reached by any society, but recognized by an increasing number of individuals—is a stage in which the members of the group consciously co-operate for the common good.

Mr. Aldrich bases his conclusions on the so-called gregarious instinct in man and on the existence of a

[4] *The Primitive Mind and Modern Civilization*. By C. [illegible] Roberts Aldrich. With an introduction by Bronislaw Malinowski, Ph.D., D.Sc., and a foreword by C. G. Jung, Dr. med. et Jur. The International Library of Psychology, Philosophy and Scientific Method. London: Kegan Paul, Trench, Trübner and Co., Ltd.; New York: Harcourt, Brace and Co. 1931. (Pp. xi + 249. 12s. 6d. net.)

racial unconscious, coming thereby perilously near the concept of a group mind which Professor Levy Bruhl predicated, despite his critical disavowal of the tenets of the French school. We are prepared to recognize that the welfare of the individual is bound up with the welfare of the group to which he belongs, but that does not imply that the group is an entity except as an aggregate of individuals. That there can be a racial unconscious is entirely disputable, and to talk of a collective morality inherent in the laws of life is to attribute to the natural processes of evolution a human rationality of purpose for which biology provides but little justification. We can find indeed, no evidence whatever in modern anthropology for the gregarious instinct on which Mr Aldrich bases his hypothesis of a primitive horde and can find no logical explanation for the development of family life from such a horde if it ever existed. On the other hand all the evidence points to the family as being the original unit extending later to the clan and so into the tribe, with the natural corollary that marriage as an institution regulating the lives of individuals was recognized in the earliest stage of human culture. Theories of group marriage and primitive promiscuity have been long abandoned by our leading anthropologists. It is incorrect, we believe to say with the author that love as moderns know it the passionate preference of one woman to all others or of one man to all other men, is not known to the primitive for whom every woman is about the same as every other woman provided she is not too old. Suicides caused by disappointment or thwarted love are too frequent in primitive societies to allow such an assertion to pass unchallenged.

In our view, then the premisses on which Mr Aldrich builds are unsound, but that does not detract from the great interest and stimulation to be derived from this volume. There are many points of anthropological detail on which we feel bound to disagree like the alleged ignorance of paternity for which both the Australian and Trobriand evidence is not sufficiently convincing. He unduly depreciates the intellectual curiosity of primitives, and his explanation of the reason why sexual and other taboos are relaxed on ritual occasions is far from complete. But despite these and other points of disagreement, we have found the book provocative of thought and it should be of real value to the critical student of primitive psychology. In discussing the difficulties of language and interpretation Mr Aldrich makes a new and excellent point which goes far to explain our frequent misunderstandings of to us, illogical identifications in primitive cultures. He points out that we use the copula 'is,' instead of some word like "acts," which is really more what the primitive means. When he says that *x is y* he is really saying *x* acts like *y* or has the same effect as *y*. Mr Aldrich might have added that in many primitive languages the word for 'is' expresses not the copula (which does not exist), but a state or function.

THE A.A.M.S.

'The Australian Army Medical Services, Vol. I,'* deals with the Gallipoli campaign, the campaign in Sinai and Palestine, and the occupation of German New Guinea. In each case it is more than a description of the Australian Medical Services, it is a study of the medical problems connected with each campaign. Thus, in following the Gallipoli campaign, the author has surveyed the whole sphere of activities from the beaches of Anzac to the base hospitals of Egypt and Malta. The complications caused by the division of executive responsibility between the Navy and Army, according as the evacuation was on sea or land are at once apparent. In these combined naval and military operations new difficulties arose which in many instances were entirely unforeseen and had not previously been studied. Even to-day comparatively little has been written about this intricate subject. The necessity of preserving a clear line of evacuation is at once obvious and in these pages it is now clearly demonstrated how a want of preparation combined with inadequate facilities and congestion in base hospitals, was responsible for slowing down the evacuation from the front line. The portion dealing with the Palestine and Sinai campaign records the work of the medical services with mounted troops with careful attention to detail. As much of the ground covered is new this is certainly not the least interesting part of the present volume.

The experience of the Australian Imperial Force was similar to that of the British Army as a whole. Similar problems were encountered and their solution was determined by the same principles and policy. It may be claimed that the experiences of a self contained homogeneous force of the size of the A.I.F. can be more easily collated than those of the vast armies of Europe and so may be of value in illuminating the obscurities of a larger field. The administrative and regimental officers of the medical services of the Australian military forces were almost without exception civil practitioners with only militia training at most. These suddenly became responsible for the medical side of a great military organization. In many instances their first business was to grasp an understanding of their new duties from such experienced soldiers as were available. Once familiar with their new sphere of activity they became in turn the instructors, bringing fresh minds and methods to consider and solve old questions so that the whole medical services of the Crown regular and irregular benefited by their stimulus. No one doubts that one reason for the high state of efficiency of the medical services of the Crown during the war, was the receptiveness of the regular soldiers to suggestions from the highly efficient temporary medical officers from home and from the oversea Dominions. The object of the book is at once historical and instructional, so that should a similar emergency arise in the future, a new generation may face the fresh crisis with a clearer knowledge of the principles of medical strategy and tactics than did their predecessors in 1914–18.

The authors of this first volume of the *History of the Australian Army Medical Services* are to be congratulated on fulfilling their task in a thoroughly satisfactory and lucid manner. All three parts of the present work are full of valuable information, and are well written in a clear, instructive style. The volume is to be recommended, not only to those interested in the various military problems presented and in the account of their solution, but also to those students of military history who would read again, from another angle, the story of the Australians in the great war.

NOTES ON BOOKS

The fourth edition of *Roentgen Interpretation. A Manual for Students and Practitioners*† by HOLMES and RUGGLES is welcome. The subject matter is brought up to date more particularly in connexion with bone pathology and the recent developments in the examination of the genito-urinary tract. There is no better book for students and practitioners they will find in it accurate information regarding radiological technique and diagnosis. The authors lay great stress on a thorough knowledge of

* *Official History of the Australian Army Medical Services in the War of 1914–1918.* Vol. I. Edited by Colonel A. G. Butler, D.S.O., V.D., B.A., M.B., Ch.B., A.A.M.C. Melbourne: Australian War Memorial. London: Australia House. (Pp. xxvi + 873; 228 illustrations, maps and graphs. 21s. 6d. post free.)

† *Roentgen Interpretation. A Manual for Students and Practitioners.* By George W. Holmes, M.D., and Howard L. Ruggles, M.D. Fourth edition, thoroughly revised. London: H. Kimpton, 1931. (Pp. xii + 333; 237 figures. 21s. net.)

The fee charged for tonsillectomy is 50 dollars, plus hospital expenses, and, owing to the high costs, the correction of physical defects is unsatisfactory. Private nurses charge from 6 dollars a day of twelve hours. The medical relief of poor people is evidently very incomplete, and not satisfactory; but it would appear that recent legislation is likely to result in much improvement in this direction. In certain districts deplorable social conditions, of which examples are quoted, exist, which would not be permitted in Great Britain.

Health education in the schools requires to be developed, but good progress has been made with systematic instruction in food values and in the orthopaedic treatment of school children. The county health demonstration programme has met with considerable opposition from certain medical practitioners, who object to lay control, and have made charges of "ineptitude," "extravagance," "pauperism," etc., against the scheme; but most readers of his review will agree with Dr. Winslow that many of the complaints have no justification.

This survey of rural hygiene can be strongly recommended to public health workers in Great Britain, for it shows what can be done in an area undeveloped so far as essential health services are concerned, and it also sets forth clearly the difficulties that have to be overcome, many of which do not exist in this country or have already been overcome.

JOHN HUNTER'S BUFFALOES

John Hunter collected, as is well known, animals "of the strangest selection in nature" in the grounds of his country house at Earl's Court; and Jesse Foot, in his scurrilous *Life of Hunter*, describes "those buffaloes which Hunter so lately as in 1792 put into harness and trotted through the streets of London." To insinuate that this was for advertisement, Foot suggests that Hunter can never have judged "that he might have been fairly outrivalled by a showman's dromedary, especially if there were, and probably there would be, the additional effect of a monkey mounted on his back—playing its little antic tricks." This impudent fancy is the subject of one of the most amusingly mischievous of Foot's *Illustrations to the Life of Hunter*, now in the Wellcome Historical Medical Museum. On the left of the drawing is the showman with his monkey riding on the dromedary, and to the right Hunter stands in a low two-wheeled cart drawn by a pair of small dark buffaloes.

William Clift came to Hunter's household in this year (1792), and, as might be expected, he has left a more veracious account of the buffalo cart. In 1816 Clift, being then Conservator of the Museum, drew up a manuscript catalogue of the Hunterian pictures at the Royal College of Surgeons. The first item in this catalogue, which is now in the College library, happening to be "A drawing of three Buffaloes (Zebus) from the East Indies, which were in Mr. Hunter's possession alive," Clift wrote out the following amusing story.

These Zebus were alive in Mr. Hunter's possession at Earl's Court, Kensington, in 1792-3, and used to be driven, or rather led, in a cart to 13 Castle Street Leicester Square with Vegetables for the service of the Family every Wednesday; and in return took back the Stable Dung produced ad interim—and during the Winter Season the off-fall from the dissecting-rooms. The large white Animal was the Leader: the two small ones in the Double Shafts. On one (and only one) occasion, on there being a *new* Carter, a wildish Scotchman, who was known by the Cognomen of Scotch "Wolly" (Tom Barton having been discharged for Drunkenness) he first brought the dissecting room Hampers *into the street* in the Cart *without covering them as usual with the Stable Dung;* and *as usual* went into the Kitchen to get his highland Crop filled with Beef and Beer:—In the meantime, some of the boys of the neighbouring school of St. Martin's parish, opposite the Mews Gate, and other Street Boys, being *aware* that Apples and other fruit were usually brought from Earl's Court, soon mounted the sides of the cart (the Buffaloes being taken during the time into the stables *behind*) to explore the Contents of the Hampers. The first object that struck their *attention*, instead of the Apples they *expected*, was the *Putrid* half dissected arms of a Man, green blue & yellow;—Livers, intestines & other parts,—and the disappointment occasioning some demur and disappointment as well as remark to the street passengers, every one of whom took a peep, and consequently a numerous Audience was soon collected to witness the Prelections and Demonstrations of a Hair-Dresser's assistant who put himself very forward in the Discussion, which being carried on in a very audible manner, presently attracted the notice of the Inmates of the Dissecting rooms (which were the Attics of No. 13, Castle Street): who soon came to the Rescue, on my application, in their dissecting dresses. . . . We soon disturbed the Carter from his dinner, and his first essay was to put his cattle to the cart, but the haloo-balloo was too great to succeed in that attempt—the cart was run into the coach house and the doors attempted to be shut:—the buffalo being held outside with the halter between the two halves of the Door; the before-mentioned hair dresser in his white jacket and apron with pockets and paraphernalia of razors & powder puff attempted to *cut* the Halter and set the buffalo loose: but the noble beast made a dead set at him, and fortunately pinned him to the door *between* his horns instead of *on* them: the Scotch Willy was pushed out and the Door closed;—the Buffalo ran down the street, turned up Green Street, and ran round Leicester Square with the man holding on at the end of the long halter, to the great amusement of the crowd who by degrees dispersed, and in the evening the cart was dispatched minus the Hampers, and *so ended* the affair: the carter never knowing what we had placed in his cart, until long afterwards: as Peter Shields the Head Gardener at Earl's Court always superintended the *return* of the cart and quietly disposed of whatever was transmitted *from* London in *return* for the good things he had *sent* to us.

The before mentioned "Wolly" some time afterwards having returned to Earl's Court with the usual cargo of Hampers and stable-dung, took upon himself the responsibility of shooting the contents of his cart of *Stable Dung* on the Dunghill, in a very retired situation at the back of the Premises, without being aware of what his cart contained, and without having consulted the *Head Gardener*. To his utter amazement on the Capsizement or Capsission of the contents of his cart the Hampers contained *such things* as utterly capsized his wits and his appetite:—The following is a nearly *word for word* description of the Dialogue which occurred between the before-named "Wolley," and excellent, kind-hearted Mrs. Shields the Gardener's Wife:—

——"Why, Wolly, what's the matter wi' ye, the day, my mon?

——Ahé, Missus, woman, Ive had *sic a turn*!

——Why, what the De'el ails ye Man: ye seem a' through other!

——Ahe, Missus—what d'e think? On shooting out my keart, what did I see, but a Man's fut wi' a' the tane tae tall't. Ahe, it gie'd me *sic a Turn* that I went to the *Pub*, and got a glass o' Gin, and a pot o' porter, and a quarter o' cheese, and a twa-penny loaf: I was parfectly horrefeed and astoonded! I was parfectly bewilldert!!

——Weel, weel! Wolly my man, It wonna do that ye should ha' *sic a turn* every day! y'er shilling a day wou'd'nt admit o't!!!"

W. CLIFT

The little comedy of the "hair-dresser's prelections" needs no comment; but it is interesting to note the list which Clift gives (in his MS.) of the "dissecting-room inmates" and pupils of Hunter at this time. "Scotch Willie" is entered among the Earl's Court outdoor servants in Clift's list of Hunter's dependants, which was printed in the *British Medical Journal* (1890, i, 739). In this list he was described as "half-witted" and "employed in the fields"; but this was evidently before his promotion, for the list also includes "Tom Barton, carter." The story, in accounting for the buffaloes' weekly journeys, satisfactorily disproves Foot's insinuation that Hunter in person drove the buffalo cart from Earl's Court to Leicester Square, "trotting through the streets of London."

THE SCIENTIFIC WORLD-PICTURE

The scientific world-picture of to-day, which formed the theme of General Smuts's presidential address on September 23rd at the centenary meeting of the British Association, is of more than purely scientific interest; the conclusions of science as to the nature of the universe are felt by everyone to be closely connected with our views on human destiny, and a recognition of their import is not confined to scientific circles. A hundred years ago the discussion of this subject could hardly have been approached without arousing considerable heat, and it may be reckoned among the distinctive advances made in the period that all traces of acrimony have disappeared in the reception and discussion of problems of this nature. On all sides our limitations are now more fully appreciated, and we are beginning to realize, what Herbert Spencer endeavoured to teach, that our knowledge is relative, that we only know in part, and that whatever picture of the universe we form must necessarily fall short of the reality. Moreover, the picture itself is subject to change with changing knowledge, and, as General Smuts recognizes, that of to-morrow will not be that of to-day. Our conceptions of the universe are therefore admittedly conventions, yet not mere academical products, since they serve a practical purpose in satisfying human cravings, providing, as they do, passable explanations of the purpose of human life on the one hand, and on the other representing the results of natural, innate efforts to bring observed facts under some consistent generalization. From the former tendency the theological systems have arisen, from the latter the succession of world-pictures which characterize the several phases of scientific history.

Conceptions of the constitution of the universe prevailing a hundred years ago, and (with some protest) accepted in the main almost up to the present time, have recently been revolutionized by additional knowledge acquired about the nature of matter and space. As regards matter, the fact is now familiar to most that it consists of energy or a combination of energies, and its recognition has removed a difficulty felt in the attempts to reconcile our ideas of mind and matter; an apparent distinction in kind seemed to exist, rendering their relationship inscrutable. If, however, mental processes may be regarded as manifestations of energy, the distinction disappears, and it is possible, as General Smuts suggests, that physical and psychological processes may in the future be submitted to similar lines of investigation and be of mutual assistance in the discovery of their underlying laws. However this may be, the old material interpretation of the universe has been abolished.

The recent advances have, further, fundamentally altered our standards in regard to the entities with which physical science is concerned. Mass, for example, which we have always regarded as a constant and unchangeable property of a body, has been experimentally proved to be variable. Similarly with notions of space: we were wont to consider the space between two points as being constant as regards, for example, its property of permitting the transmission of light in a straight line only. But it is now known to be variable in this respect, compelling, it may be, the route traversed to take a curved instead of a rectilinear form. Space can therefore no longer be represented in linear terms merely; the deviations from the straight line, varying at different instants in correspondence with the character of the curve, necessitate the introduction of the notion of time, in addition to that of distance, in our definition. Thus the conception of a new entity—space-time—has arisen, the far-reaching significance of which may be realized from the fact that other physical entities have come to be considered as mere configurations of space-time. It is admitted that the steps by which this transformation has been brought about are beyond the comprehension of the layman, and cannot, according to General Smuts, be understood without the aid of the most abstruse mathematics, and, even so, not without a due regard to "epistemological" considerations. In this particular, therefore, the layman must rest content with mere adumbrations of the truth. As a consequence of this transformation, the flexible and variable continuum called space-time, which takes the place of our old notion of space, must, as stated by General Smuts, be regarded as the only physical reality in the universe, and its curvatures and unevennesses are held to constitute what to our senses appears as the material world.

Space-time, then, remains as the sole medium in which the scientific world-picture has to be delineated, and General Smuts has attempted the delineation in his theory of holism. From the flexible and variable properties of space-time we derive our sense of the distinction of one object or process from another, and of the whole world of phenomena. Observation, however, reveals the fact that phenomena do not present themselves in haphazard fashion, but as associated in definite patterns or configurations, producing the impression that they are under the control of some dominating principle. In other words, they appear to be organized. From this conclusion certain deductions follow, arising from considerations as to the nature of organization. In an organized structure we are apt to regard the individual parts as merely juxtaposed and exercising their influence on the whole merely through this juxtaposition. It would seem, however, that this is in reality merely a conventional mode of thought, adopted through the necessities of language, and that each individual part of an organism would be more correctly regarded, not as a detachable segment, but as having lost its individuality, and become merged in the whole, and in this sense as being co-extensive with

the whole. This conception is evidently applicable not only to an object and its parts, but also to objects and their environment, and consequently to the whole universe. Starting with space-time as the physical basis of the universe, the theory of holism (ὅλος, solidus, whole or entire) apparently depicts the universe as an organic whole in this sense—on the one hand the flexible physical continuum of space-time, on the other hand the dominating and active principle of organization working within it. It is evident that such a theory leaves room for, and indeed facilitates, the conception of evolution and the progressive development of a sense of moral, religious, and aesthetic values foreshadowed in General Smuts's eloquent and illuminating address.

STUDIES ON THE ETIOLOGY OF RICKETS

The Scandinavian periodical *Acta Paediatrica*[1] has recently published as supplements three important papers dealing with the etiology of rickets. In the first supplement Dr. T. Skaar reports the results of an extensive series of experiments on dogs. The animals were fed on a variety of rachitic diets, and estimations were made of the intake, excretion, and serum content of calcium and phosphorus for periods extending over several months. The paper contains a large amount of interesting biochemical data. One of the most noteworthy of the conclusions is that lack of vitamin D and vitamin C causes both the phosphorus and the calcium balances to be negative.

The second supplement contains a report of clinical and experimental studies by Drs. K. U. and G. Toverud upon mineral metabolism during pregnancy and its bearing on the disposition to rickets and dental caries. The paper contains a mass of data on the mineral metabolism of pregnant women, of pregnant bitches, and of puppies. The authors show that the calcium and phosphorus requirements during the last part of pregnancy are much higher than is generally recognized, and they find that negative Ca and P balances often occur at this period owing to the deficient mineral content of the diet. Other factors, and particularly a deficiency in vitamin D, may play a part in producing this negative balance. The authors conclude that a mineral and vitamin deficient diet during pregnancy and lactation predisposes the offspring to rickets and dental caries. They have investigated the effects both of varying the calcium and phosphorus intake, and also of administering cod-liver oil. They conclude that the minimum daily requirements during the last part of pregnancy are 1.6 grams Ca and about 2 grams P. Unless these amounts are available, there is a negative mineral balance. They recognize the value of cod-liver oil, especially during the winter months, but show that this cannot compensate for an absolute deficiency of minerals in the diet. Since about three-quarters of the calcium intake is derived from milk, the problem is very largely one of adequate milk supply. The authors state that the average milk consumption of the cases investigated did not exceed 500 to 600 c.cm. (0.9 pints) per diem, and that nearly a litre ($1\frac{3}{4}$ pints) is needed. These figures for milk consumption are higher than would be obtained in Britain, and similar investigations here would probably show a more acute calcium deficiency in pregnant and lactating women.

The third supplement is of peculiar interest, because the author, Dr. J. Kloster, has served as district physician in the Varanger Fiord that lies to the east of the North Cape. He has investigated the distribution and frequency of rickets in the little fishing villages of this coast. The inhabitants of this isolated district live on a practically unvaried diet of fish, and their chief source of fat is fish-liver oil. It is therefore somewhat startling to learn that 43 per cent. of the children are rachitic. Moreover, it may be mentioned that in many cases the disease is severe, for photographs are reproduced which show serious deformities. The author has made a careful analysis of the possible causes of this prevalence of rickets. Analysis of the distribution of the disease in nine fishing villages shows remarkable variations; its incidence varies in different villages from 17 to 75 per cent. among children under school age, and from 8 to 31 per cent. among school children. There are certain factors disposing to rickets that affect the whole community. Chief of these is lack of sunlight, for the district lies within the Arctic Circle, and the sun does not appear during two months of the winter; moreover, throughout most of the year the climate is rigorous, and the children get very little fresh air. The district is inhabited by three races—Lapps, Quains and Norwegians—and this provides an opportunity for testing the influence of general hygiene upon the incidence of rickets. The Lapps live in dirty and unventilated mud cabins and seldom wash, while the people of the other two races live in fairly comfortable cottages and have a high standard of cleanliness. The incidence of rickets among the Lapps is, however, considerably lower than it is among the other races.

Dr. Kloster concludes that diet is the most important factor in the prevention of rickets. The population of the Varanger Fiord live on fresh and salted fish, and this diet is very unbalanced in respect of its mineral content, for it is low in calcium and contains an excess of phosphorus; moreover, the salt fish naturally contains a large amount of NaCl. It is usually agreed that three factors influence the occurrence of rickets—namely, light, mineral balance, and vitamin supply. The author shows that the people inhabiting this coast live under extremely unfavourable conditions as regards the first two. Analysis of the habits of the different villages reveals that the incidence of rickets depends chiefly on the amount of fresh fish eaten. Rickets is worst in the village of Skallelv. The inhabitants here are pro-

the whole. This conception is evidently applicable not only to an object and its parts, but also to objects and their environment, and consequently to the whole universe. Starting with space-time as the physical basis of the universe, the theory of holism (ὅλος, solidus, whole or entire) apparently depicts the universe as an organic whole in this sense—on the one hand the flexible physical continuum of space-time, on the other hand the dominating and active principle of organization working within it. It is evident that such a theory leaves room for, and indeed facilitates, the conception of evolution and the progressive development of a sense of moral, religious, and aesthetic values foreshadowed in General Smuts's eloquent and illuminating address.

STUDIES ON THE ETIOLOGY OF RICKETS

The Scandinavian periodical *Acta Paediatrica*[1] has recently published as supplements three important papers dealing with the etiology of rickets. In the first supplement Dr. T. Skaar reports the results of an extensive series of experiments on dogs. The animals were fed on a variety of rachitic diets, and estimations were made of the intake, excretion, and serum content of calcium and phosphorus for periods extending over several months. The paper contains a large amount of interesting biochemical data. One of the most noteworthy of the conclusions is that lack of vitamin D and vitamin C causes both the phosphorus and the calcium balances to be negative.

The second supplement contains a report of clinical and experimental studies by Drs. K. U. and G. Toverud upon mineral metabolism during pregnancy and its bearing on the disposition to rickets and dental caries. The paper contains a mass of data on the mineral metabolism of pregnant women, of pregnant bitches, and of puppies. The authors show that the calcium and phosphorus requirements during the last part of pregnancy are much higher than is generally recognized, and they find that negative Ca and P balances often occur at this period owing to the deficient mineral content of the diet. Other factors, and particularly a deficiency in vitamin D, may play a part in producing this negative balance. The authors conclude that a mineral and vitamin deficient diet during pregnancy and lactation predisposes the offspring to rickets and dental caries. They have investigated the effects both of varying the calcium and phosphorus intake, and also of administering cod-liver oil. They conclude that the minimum daily requirements during the last part of pregnancy are 1.6 grams Ca and about 2 grams P. Unless these amounts are available, there is a negative mineral balance. They recognize the value of cod-liver oil, especially during the winter months, but show that this cannot compensate for an absolute deficiency of minerals in the diet. Since about three-quarters of the calcium intake is derived from milk, the problem is very largely one of adequate milk supply. The authors state that the average milk consumption of the cases investigated did not exceed 500 to 600 c.cm. (0.9 pints) per diem, and that nearly a litre (1¾ pints) is needed. These figures for milk consumption are higher than would be obtained in Britain, and similar investigations here would probably show a more acute calcium deficiency in pregnant and lactating women.

The third supplement is of peculiar interest, because the author, Dr. J. Kloster, has served as district physician in the Varanger Fiord that lies to the east of the North Cape. He has investigated the distribution and frequency of rickets in the little fishing villages of this coast. The inhabitants of this isolated district live on a practically unvaried diet of fish, and their chief source of fat is fish-liver oil. It is therefore somewhat startling to learn that 43 per cent. of the children are rachitic. Moreover, it may be mentioned that in many cases the disease is severe, for photographs are reproduced which show serious deformities. The author has made a careful analysis of the possible causes of this prevalence of rickets. Analysis of the distribution of the disease in nine fishing villages shows remarkable variations; its incidence varies in different villages from 17 to 75 per cent. among children under school age, and from 8 to 31 per cent. among school children. There are certain factors disposing to rickets that affect the whole community. Chief of these is lack of sunlight, for the district lies within the Arctic Circle, and the sun does not appear during two months of the winter; moreover, throughout most of the year the climate is rigorous, and the children get very little fresh air. The district is inhabited by three races—Lapps, Quains and Norwegians—and this provides an opportunity for testing the influence of general hygiene upon the incidence of rickets. The Lapps live in dirty and unventilated mud cabins and seldom wash, while the people of the other two races live in fairly comfortable cottages and have a high standard of cleanliness. The incidence of rickets among the Lapps is, however, considerably lower than it is among the other races.

Dr. Kloster concludes that diet is the most important factor in the prevention of rickets. The population of the Varanger Fiord live on fresh and salted fish, and this diet is very unbalanced in respect of its mineral content, for it is low in calcium and contains an excess of phosphorus; moreover, the salt fish naturally contains a large amount of NaCl. It is usually agreed that three factors influence the occurrence of rickets—namely, light, mineral balance, and vitamin supply. enough to afford large motor boats, and hence carry their catches during the fishing season direct to larger ports, while in the winter there is scarcely any fishing, because the village faces the open sea ; hence the women and children get very little fresh fish and live for the most part on salt fish. Rickets is lowest in the poorest hamlets at the head of the fiord, for here the inhabitants go out in rowing boats all the year round, and thus obtain a continuous supply of fresh fish. The author holds that the evidence he has collected supports strongly the view that an adequate and regular supply of vitamin D is the most important factor in the prevention of rickets in this district. He suggests that salt fish may tend to produce rickets, and offers no opinion as to whether other parts of fish besides the liver have any antirachitic action. Those interested in the production of cod-liver oil have long known that rickets was prevalent on this coast, but until now it has been unexplained. This careful analysis of the incidence of the disease does much to dispel the mystery.

A CONSPECTUS OF HOSPITALS

That familiar work of reference, *Burdett's Hospitals and Charities*, after forty-two years' useful existence, has been embodied in rearranged form in a new publication, *The Hospitals Year Book*,[1] which incorporates, also, the statistics issued in the annual reports of the King Edward's Hospital Fund for London and the Central Bureau of Hospital Information. The result is the most comprehensive survey of the British hospital system, municipal as well as voluntary, that has yet appeared. The statistical information is conveyed in 139 tables packed with figures, and the directory portion, which includes particulars concerning even the smallest and most local institutions, spreads itself over 370 broad pages. We learn that 60 per cent. of the voluntary hospitals in London, 76 per cent. of those in the provinces, and 86 per cent. of those in thrifty Scotland ended the year 1929 with a credit balance on their maintenance account. The income per available bed in London hospitals having over 100 beds was £245 ; in the hospitals having fewer that 100 beds and more than 30 it was £208, and in the smallest hospitals, with fewer than 30 beds, it was £192. The corresponding figures for the provinces were £155, £138, and £131. Voluntary gifts are still the largest source of maintenance income, patients' contributions coming next (except in Scotland), and interests on investments third. The number of beds for private patients in London hospitals is 1,340, the charges ranging from three to six guineas weekly. In the largest of the hospitals under construction at the present time, Bradford Royal Infirmary, with 406 beds, there is to be a special block for 70 private patients.

The volume of work accomplished under the voluntary system is amazing. At 929 hospitals, with 69,202 beds, the total number of new in-patients during 1929 was over one million, and of new out-patients five and a quarter millions. The normal annual rate of increase under the voluntary system is about 1,500 beds, 40,000 in-patients, and 150,000 out-patients. The figures for out-patients are interesting in view of the discussions recently on the out-patient problem. More than one-third of the total number of out-patients are treated at the 32 hospitals which have medical schools. The comment is made—which we take to express the view of the British Hospitals Association, under whose auspices the annual is issued—that surely the same limitation of admission to the out-patient department should apply as already applies with regard to admission to the wards, where no one upholds the doctrine of the " ever open door " for in-patients. Except in cases of emergency, admission to the ward is definitely limited within well-known boundaries. Why not an equal limitation in the out-patient department? Out-patient clinics for persons suffering from mental illness are the subject of an interesting footnote. The experience of one provincial mental clinic is quoted, in which, apart from patients of the neighbouring mental hospital who had been released on parole, 83 patients were dealt with during the year, 13 of whom were found to be suffering from deficiency in mental development, 10 from organic disease of the nervous system, 27 from functional psychosis, and 33 from psychoneuroses and neurosis.

Figures are barren things without imagination to clothe them, but there is a certain impressiveness in 600,000 operations under a general anaesthetic being done in a year in 600 provincial hospitals alone. The average weekly cost of in-patients seems to vary widely, even among hospitals otherwise comparable. Thus, at Charing Cross it is £3 17s. 3½d., and at Middlesex £5 4s. 7½d. At Hampstead General Hospital the figure is £4 7s. 7¾d., at Bristol Royal Infirmary £2 18s. 9d., and at Radcliffe Infirmary, Oxford, £3 5s. 10½d. The average cost for each out-patient attendance is given as 2s. 2.18d. at St. Bartholomew's, at West London Hospital 1s. 3.46d., at Addenbrooke's Hospital, Cambridge, 1s. 6.25d., and at Plymouth, South Devon, and East Cornwall Hospital it is as low as 4.64d. These wide variations suggest that different methods have been adopted in computing " overheads." The hospital in London which has the largest medical staff is St. Bartholomew's, with 84, followed by St. Thomas's, with 81 ; but in the provinces, Manchester Royal Infirmary has 95, and in Scotland, Glasgow Royal Infirmary has 113. Among municipal and public assistance hospitals, the largest medical staff is at Stobhill, Glasgow, with 17 officers. The London Hospital has the largest nursing staff of a voluntary hospital in the metropolis, numbering 490. In the provinces, Manchester Royal Infirmary heads the list with 228, and in Scotland, Edinburgh Royal Infirmary, with 431. The largest nursing staff at a municipal hospital (as distinct from mental hospitals, where the male and female attendants may reach four or five hundred) is 300 at Belfast General Infirmary, followed

by 282 at Stobhill, 275 at Crumpsall, Manchester, 268 at Hope, Salford, and 266 at Walton, Liverpool. Another feature of this informative volume is a list of contributory schemes and organized workmen's collections; they number 280, but it is not suggested that this is complete. Wherever one dips into this compilation some interesting point is brought to the surface: the experience of hospitals with rubber flooring, the time at which work commences in the wards, laundry charges in hospitals, working arrangements in *x*-ray departments, salaries and emoluments of dispensary staffs, materials used for the walls of recently constructed operating theatres, ratio of operating theatres to beds for surgical cases, and so on. The information has been painstakingly collected and is clearly set out.

RECENT RESEARCH ON DIPHTHERIA

The recent increase in the death rate of serum-treated diphtheria patients recorded in certain areas, particularly in Central Europe, still remains unexplained. One hospital in Berlin had a death rate of over 20 per cent., yet Bie in Copenhagen reported less than 5 per cent. While most writers state that they cannot reach any easy explanation, some suggest that antitoxin is efficacious if properly used (that is, early and in adequate doses), while others are inclined to throw some blame on antitoxin. Husler[1] in Munich investigated sixty severe attacks with forty-five deaths; only twenty-three of the patients were given serum on the first day on which they were seen by a medical man, and in twenty-five instances serum was delayed more than two days. Pockels[2] also relates that not one of forty-four patients who died had received serum on the first day of illness, and but two on the second day. This delay—at first sight a grave reflection on the practitioner—is attributed, at least in part, to difficulty of diagnosis caused by an unusual appearance of the throat, with such congestion of the tonsils that the throat and the membrane behind could not be seen. Some authors blame the general lowering of social standards and care of infants, carelessness of the parents, objection by parents to giving antitoxin, or the cost of antitoxin. Among those who incriminate antitoxin, a small number affirm that concentrated serum is deficient in certain mysterious natural curative properties; others say that the type of the disease has changed, the clinical picture is different, and that some new antitoxin is called for to combat the increased malignity of the bacilli now prevailing. A new note has been added to the discussion by the investigations of Anderson, Happold, McLeod, and Thomson.[3] They suggest that there are two main groups of diphtheria bacilli causing the disease, *gravis* being responsible for toxic attacks with a high death rate, and *mitis* for mild attacks with a low death rate; while the intermediate group is less often found and of less importance. It is certainly odd that diphtheria bacilli have not previously been divided into two clear-cut groups—those that do, and those that do not ferment starch and glycogen—which these workers describe. But the serologist will not yet be wholly convinced. He will note that the Leeds workers weight their argument by including amongst the *mitis* strains a number that are avirulent; even with this loading—while it is true that in fifteen of the sixteen severe attacks *gravis* was found—the percentage (33) causing "moderately severe" attacks was the same for both types, and 36 per cent. of the *gravis* strains were obtained from carriers or from patients suffering from "slight" attacks or from rhinitis. In testing virulence by the intracutaneous method in guinea-pigs, the severest lesion "very marked" was caused only by *mitis* strains. During the past few years a number of strains from "hypertoxic" attacks in Europe have been examined in various Continental and English laboratories; all were completely neutralized by ordinary concentrated antitoxin, whether culture or toxin was used. No unusually high virulence could be detected. Obviously, final judgement must await further work. There is little evidence to suggest that ordinary concentrated antitoxin has failed to save patients treated during the first day of illness, or that, if given intravenously in full doses early in the disease, it has failed. Until it has been clearly shown that diphtheria bacilli, obtained from instances of suspected failure of serum treatment, resist ordinary commercial antitoxin, the clinician may safely await the result of further research.

CENTENARY OF THE BRITISH ASSOCIATION

The British Association for the Advancement of Science was founded on September 26th, 1831, with a view to affording a common meeting-ground for "cultivators of science," to calling the attention of the educated public to the progressive discoveries made by investigators, and to the instituting of annual meetings throughout Great Britain at first, and latterly in the Dominions also. London has always been definitely excluded as a meeting-place until now, because the majority of the British learned societies assemble there annually, but it was felt that this rule should be broken in the centenary year. The British Association owed its origin in great measure to the Yorkshire Philosophical Society, and it was in York that the Association held its first meeting, under the guidance of the principal officers of that society. Reference is made in this issue at page 575 to the presidential address of General Smuts, and we hope next week to publish a report of some of the papers and discussions which have special medical interest. A beginning was made by each of the thirteen Sections on Thursday, and certain of the proceedings in the Sections of Physiology and Psychology deserve mention. In the first of these a discussion on the physiological basis of sensation was opened by Professor E. D. Adrian, F.R.S., who remarked that, although the events in the brain which caused sensation were still uncertain, knowledge was now available as to the kind of messages transcribed by the sensory nerves, for they could be detected electrically. A succession of impulses passed along the nerve fibres, each being a brief surface reaction, which spread down the fibres accompanied by a change of electric potential. Their frequency varied with the intensity and abruptness of the stimulus, but in any one fibre they were all alike, and they were of the same general type in all nerve fibres. In its main outline the working of the sensory apparatus seemed to depend on fairly simple physical and chem-

changes, but many outstanding lines of investigation required to be followed before an explanation could be obtained of the variety of sensations which were experienced. Dr. C. S Myers, F.R.S., thought, however, that relatively little light could be thrown on the physiological basis of sensation by studying the sensory nerve fibres of the sensory end-organs The more important cerebral sensory centres were essential for sensation, though they must not be regarded as its seats. Sensation depended on the relation of their activity to that of the vast integration of central nervous activity on which "self-activity" was dependent; where no "self-activity" was involved there could be no consciousness of sensation. Dr. Myers discussed the differentiations of sensations, and thought they might be fundamentally classified as "clonic" and "tonic." On the future study of the integration of these two (and perhaps other) elementary classes of sensation, and of the central impulses involved, depended the obtaining of further additions to our knowledge of the physiological basis of sensation In the Section of Psychology, Professor C W Valentine discussed the methods of experiment and observation in the psychology of early childhood He gave illustrations of the ways in which artificial experiments should be associated with careful observation of the child's reactions to ordinary daily events in order to deduce general principles as well as individual characteristics. Thus at the age of 2 or 3 years anger and pugnacity were distinguishable from each other, there was a clear difference, also, between self-assertion and self-display. Some mental capacities at their earliest dawn seemed to depend on the energy supplied by spontaneous momentary interest. Dr. Shepherd Dawson, speaking on intelligence and fertility, said that there was a small but significant negative correlation between the intelligence of the child and the size of the family The birth rate was higher in families represented by the dull children, and although the deaths were also higher, the number of survivors was greater He suggested the possibility of there being a slow, progressive, and serious dilution of intellect in the general population, and urged the need for study of the inheritance of mental aptitudes.

RESEARCH WORK IN MENTAL DISEASE

Part II of the annual report of the Board of Control for the year 1930[1] contains an account of the scientific research work which has been prosecuted in the various mental hospitals of England and Wales As in former years, a great deal of research has been carried out with a view to determining the presence of toxic or septic foci in psychotic cases. The clinical report of the Birmingham Joint Board of Research draws attention to the fact that the sources of the responsible toxaemia in cases of mental disorder are outside the scope of investigation of a single department, and that team work is therefore essential for the complete treatment of the case. Seven cases illustrative of the part played by oro-nasopharyngeal sepsis, in relation to the puerperal and post-puerperal psychoses, are quoted; and the interrelationship of appendicitis, oro-nasopharyngeal sepsis, and mental disorder is discussed in reference to these cases. A communication from Cardiff City Mental Hospital denies that there is any relationship between the psychoses and pelvic disorders, except in a very small number of cases. The effect of menstruation on the mental state is regarded as negligible, and a routine pelvic examination, except in such cases as show symptoms pointing to pelvic lesions, is looked on as not only unnecessary, but as often having an adverse effect upon the mental state, even if only temporarily. A case of acute confusional insanity due to a septic focus in the right ear, and cured by the performance of a radical mastoid operation, is reported from the Cheshire County Mental Hospital, Chester. In the ear, nose, and throat department of St Andrew's Hospital, Northampton, search made for the evidence of sinusitis has not shown that it is, as has been stated, a common condition in psychotics Among the contributions from other mental hospitals are those relating to treatment by colloidal sulphur, tryparsamide, and malaria Asylum dysentery and allied infections is again the subject of report from the West Riding Mental Hospital, Wakefield.

ECONOMIES AT GENEVA

The present demand for economy (writes our Geneva correspondent) has not left the League of Nations unaffected Delegates to the Assembly from nearly threescore countries, most of whom are experiencing national difficulties in balancing the budget, have come to Geneva determined that the League shall set an example in retrenchment It is, of course, true that the total expenditure of the League of Nations is comparatively trivial The League budget for 1932 amounts to 35,400,000 Swiss francs, or rather more than a million and a half in English money This includes the cost of the secretariat and its special organizations, the International Labour Office, the Permanent Court of International Justice, the Nansen International Office for Refugees, and all the branches of activity which have developed during the last twelve years No doubt economies could be effected in the League's work The verbosity of some of its delegates means waste of money as well as of time. Of one special committee of the League it is said that its documents have been so numerous that a pavement could be made of them on which the Polish delegates could walk from Geneva all the way back to their capital. But delegates are now pressing for "cuts," not because it will ease their own financial burdens, but because, as they say, if the League sets its house in order, it will be an example to the world The zeal for economy is, of course, admirable, but one sometimes wonders how far it is inspired by suspicion of the idealism for which the League stands It was a very lone voice, that of China, which was raised to point out that a little extra expenditure to-day might effect a great economy to-morrow Such views are not fashionable, and one feels, after listening to the debates in the Fourth Committee, which deals with finance, that there is a very real danger that before this Assembly closes, the work of the Health Organization, and of the organization concerned with the suppression of the drug traffic, together with other League enterprises, may be seriously affected The medical director, Dr Rajchman, has been strongly urged to reduce the figure of the budget of the Health Organization, in

view of the present period of stress, and of the fact that his organization will have at its disposal part of the new credits already provided for establishing a new field of health activity in China. He has agreed to consider the possibility of holding only one session of the Health Committee in 1932 instead of two sessions, but it was reported to the Fourth Committee that he was "adamant" with regard to the maintenance of the general work of the organization, pointing out that any reduction in the activities at headquarters would have an immediate repercussion on the efficacy of the work all over the world. So far a slight reduction in the appropriation for miscellaneous health inquiries has been made, but the scrutiny of the Fourth Committee is still to come. At the same time some very sincere tributes have been paid to the health work of the League. On behalf of India, Sir B. L. Mitter remarked on the considerable value to his country of the recent report of the Malaria Commission, and also said that India was in close touch with the Eastern Bureau at Singapore, where a comparative study of the problems of tropical disease was being effectively pursued. A saving is to be effected by the Permanent Central Opium Board, which will meet for only three sessions in 1932 instead of four. It is likely, also, that intellectual co-operation, another of the League's activities, will be pruned, for in that field the expenditure has largely exceeded the estimates. The League is faced with a very serious difficulty owing to States being in arrears with their contributions. Generally, in the past, the contributions in arrear have amounted to about 300,000 or 400,000 Swiss francs; last year they reached over 1,000,000 francs, and this year they stand at the astonishing figure of 1,700,000 francs, or one-twentieth of the total League budget. Formerly, only about five States were consistently in arrear; the number has now increased to fifteen. The truth is that an international organization, instead of being more or less immune from the privations to which national services are subject, experiences their cumulative effect.

MEDICAL INDUSTRIAL PSYCHOLOGY

The announcement at page 589 of the course of twenty lectures in medical industrial psychology to be given by Professor Millais Culpin and his colleagues at the London School of Hygiene and Tropical Medicine, marks an interesting development on the part of this institution, and brings into prominence a special subject that is regarded very largely as a newcomer to medicine. The whole relation of the work of the school to problems of industry will be watched with close attention. In epidemiology and vital statistics investigators from the Industrial Health Research Board have been co-operating with Professor Greenwood and his colleagues in research into the loss of working time due to minor illness of usually vague and uncertain etiology. Instruction and expert advice have been given on the methods of keeping and analysing records of loss of time, measurement of industrial wastage, etc. The physiological aspects of these problems of industry have already received and are receiving at the school specialist treatment and inquiry. The establishment of a chair of medical industrial psychology, and the placing of a course of lectures in this subject in the forefront of the programme for the coming session show that something substantial is now being done to attract the attention of the younger medical men and women of the day to these vital and largely unexplored industrial questions. A new and fascinating field of inquiry is thus opened up. The first course of lectures should attract large audiences.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS

We publish in the *Supplement* this week (p. 188), at the request of the Registrar of the General Medical Council, a list of the names of those medical practitioners who have not replied to his inquiries as to the accuracy of their postal addresses. Any practitioner, wherever resident, whose name is included in this list should communicate at once with the Registrar of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, or, in certain specified cases, with the Registrar of the Scottish Branch Council, 12, Queen Street, Edinburgh.

ROYAL SOCIETY OF MEDICINE

The new session of the Royal Society of Medicine opens on October 6th with meetings of the Orthopaedic Section and of the Finance and General Purposes Committee. The officers of the society have decided to continue the holding of special discussions, and the following subjects have been chosen for joint debates between two or more Sections: (1) diagnosis and treatment of abscess of the lung; (2) treatment of acute head injuries; (3) visceral functions of the sympathetic nervous system; (4) dangers of infection in the dormitory; (5) active immunization in virus diseases; (6) mouth-breathing and nasal obstruction; (7) actions and uses of antimony compounds. The dates of these discussions will be settled later, and announced on the weekly diary card. The annual dinner of the Society will be held on Thursday, November 12th, at the May Fair Hotel, with the president, Dr. T. Watts Eden, in the chair.

The Harveian Oration will be delivered before the Royal College of Physicians of London by Dr. Robert Hutchison on Monday, October 19th, at 4 p.m. His subject is "Harvey, the man, his method, and his message for us to-day."

Professor A. H. Burgess has accepted an invitation to deliver the John B. Murphy Oration in Surgery at the Clinical Congress of the American College of Surgeons to be held in New York on October 12th.

We regret to announce the death, on September 20th, of Sir William John Ritchie Simpson, C.M.G., M.D., director of tropical hygiene at the Ross Institute, and emeritus professor of hygiene and public health at King's College, University of London.

We have also to announce with regret the death of Sir Harry Baldwin, C.V.O., M.R.C.S., honorary surgeon dentist to the King; and of Dr. William Francis Dearden, medical officer of health for the city of Manchester, and for many years the leading figure in the Certifying Factory Surgeons' Association.

THE STATE OF THE PUBLIC HEALTH

SIR GEORGE NEWMAN'S REPORT FOR 1930

[FIRST NOTICE]

The annual reports of the Chief Medical Officer of the Ministry of Health will be documents of first importance to those who in later times come to construct the social history of the early twentieth century. They are an assessment of the state of the people, in respect not only of health and disease, but, by inference, of social and economic conditions. They describe the services that are available for protection and succour, and the achievements of medical research and of public health administration. They show how, in the course of years, owing to the application of new knowledge to the raising of the standard of living, to the energetic action of the authorities, or to causes less definitely known or not known at all, diseases which once devastated the community have almost disappeared or have lost their virulence. But the battle has only shifted its ground: new perils have arisen, new resources have to be brought into play, there are perplexing returns of forgotten visitations, and medical science has to be ever on the alert, quick to take up the new duties taught by new occasions and to adapt itself to an ever recurring emergency. In all this Sir George Newman never allows his readers to lose sight of the patient work of general practitioners of medicine. Their labours are to be seen all the time behind the interlacing strands of public health administration. The insurance medical service itself is, in Sir George Newman's view, the logical development of the public health system, and the insurance practitioner is as much the inheritor of the tradition of Simon as is the medical officer of health. Such recognition of general practitioners is well merited, but it is easy to conceive that someone else in Sir George Newman's position might have taken a more official and less liberal view.

BIRTHS AND DEATHS

The fact that this is a census year gives a greater precision to the vital statistics in the present report.[1] The population of England and Wales during the last decennium shows the lowest rate of increase ever recorded since census taking began, with the exception of the previous decennium, which witnessed the most destructive war and pestilence of modern times. The level of population has been maintained—but only just maintained—by the improvement in the rate of mortality. But this compensation cannot continue indefinitely, and by the middle of the century the population will have attained, or passed, its maximum. Not only the rate of growth, but the distribution of the population is altering. Northumberland and Durham are scarcely increasing at all, in Lancashire and Cheshire the rate of increase is very small, but in the south-eastern counties the multiplication continues. The flow of population is back towards that part of the country where the Anglo-Saxon *stock got its first foothold*.

In 1930 the children born numbered 648,811, an increase of 5,138 on the previous year. But the birth rate, 16·3 per thousand living, compares with 35·4, 32·4, and 29·9 respectively, for the last three decades of the nineteenth century. Even the average figure for the years 1926–30—namely 16·7—is well below the figure (19·9) for the previous five years. The death rate in 1930 was 11·4, which compares with 13·4 for the previous year, a year marked by a heavy death-roll from influenza, and with 11·7 for 1928. The infant mortality, 60 per thousand births, is the lowest yet reached, the figure was round about 150 in the closing years of the nineteenth century, and about 100 in the second decade of the twentieth.

Of the causes of death, diseases of the heart and circulation took first place, accounting for nearly one-quarter of the total, next came cancer and malignant disease, accounting for one-eighth, and then, in order of number, bronchitis, pneumonia, and other respiratory diseases, diseases of the nervous system, and all forms of tuberculosis. Invalidity, unlike death, cannot be statistically defined, but there is food for reflection in the statement that in 1930, among the insured population of England and Wales alone, a total of 26½ million weeks' work was lost as a result of sickness and disablement. Put more pictorially, it means that a population equal to that of Norfolk was immobilized for the whole twelve months.

MATERNAL MORTALITY

The maternal mortality returns continue to be disappointing. In 1930 the rate (4·4 per thousand births registered) showed a slight increase on 1929 (4·33). As many as 2,854 deaths of women were classed to pregnancy and child-bearing. If to these we add 774 others not so classed but returned as associated with pregnancy and child-bearing, it means that for every 179 infants brought into the world one mother's life was sacrificed. The total puerperal mortality stands at the highest figure, with the exception of that for 1928, ever recorded since the classification was introduced twenty years ago. The mortality due to puerperal sepsis (1·92 per thousand births) is greater than it ever was.

The variation of the puerperal mortality rate in different parts of the country is significant. For seven years eighteen county boroughs have had an average mortality rate of over 5 per thousand births, in eight of them the rate has been over 6 per thousand. All these boroughs, with the exception of Plymouth, are in Lancashire, Yorkshire, and Durham. The blackest spots are Rochdale (6·96), Bury (6·8), and Oldham (6·79). Sir George Newman urges the authorities of those areas in which an exceptionally high mortality has become the rule, to devote definite and special attention to the problem. He thinks that just as the differential causes of infant mortality have been ascertained and the fundamental differences established between the particular causes of death during the neo-natal period and during subsequent months, so it may be possible to classify to some extent the causes of maternal death and to consider what local action may be effective in reducing the incidence where the rate is excessively high. He adds that it is probable that public and professional opinion in the areas of excessive rate is not even yet sufficiently alive to the fact of the continued excess, and apparent apathy may be due to lack of information.

Praise is given to the local authorities, however, for making such provision under the Maternity and Child Welfare Act, 1918, as to lay the foundations of a maternity service to an extent which most readers of the interim report of the Departmental Committee would hardly appreciate. The scope and organization of the services provided vary greatly, in some areas preventive work is still backward, and in very few can the provision be regarded as practically complete, but in many a good and comprehensive system is in existence and the needs of maternal welfare are increasingly met in one direction or another.

Speaking of ante-natal clinics Sir George Newman points out that many of these have two initial defects. They do not fully secure the direct co-operation of the person, whether doctor or midwife who is to be responsible for the care of the mother at the time of delivery, and there is a difficulty in the proper staffing of the clinics. General practitioners chosen for their special experience

[1] *On the State of the Public Health*. Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1930. London: H.M. Stationery Office. (4s. net.)

have been unacceptable because there are obvious drawbacks to a system whereby such practitioners would be examining and advising the patients of their colleagues; on the other hand, whole-time medical officers of public health departments suffer as a rule under the disadvantage of being unable to keep in touch with obstetric practice. Efforts, in part successful, to diminish these difficulties have been made by a system of exchange of information with the prospective medical attendant.

The number of ante-natal centres or clinics provided by local authorities is about 860, to which must be added 189 clinics under voluntary associations. Sir George Newman thinks it possible that the ante-natal clinic, as known to-day, especially in the larger towns, may to some extent disappear, thus leaving the ante-natal supervision of maternity patients to be carried out by private practitioners, with the assistance of a relatively small number of consultative clinics, staffed by specialists. But whatever the ultimate arrangement, there will remain a need for ante-natal clinics, particularly in industrial and urban areas, for some time to come.

"The full development of pre-natal supervision will depend very greatly upon the efficiency of these clinics, not only in the quality and value of the advice given day by day to the women in attendance, but in the training and experience they are able to provide for medical practitioners, and upon the influence which they exercise upon public education in maternal welfare."

THE INSURANCE MEDICAL SERVICE

The fifteen pages of the report devoted to the working of the National Health Insurance Medical Service ought to be detached and distributed as a leaflet to the critics of that service, insured persons themselves, and others. Sir George Newman patiently reiterates what the service is and is not, the scheme of administration, and the rights of the insured person. Fifteen million insured persons are cared for by 15,714 general medical practitioners, and the astonishing thing, when one considers the wide extent of the front open for attack, is that complaints should be so few, and justified complaints almost negligible. Last year the various medical service subcommittees had occasion to investigate 234 complaints against practitioners, and only 65 of these were found to be justified. Out of ten appeals by practitioners against the decision of the insurance committee, three were successful; out of five appeals by the insured person or the approved society against the exoneration of the practitioner, none were successful. In seven cases it was reported by Insurance Committees that the continuance of a practitioner's name on the list would, in their opinion, be prejudicial to the efficiency of the service. After inquiry by a special tribunal, the Minister decided in two cases not to proceed to removal; in four he obtained an undertaking from the medical man to resign from the list; and one other case was still under consideration. What other service worked by nearly 16,000 people can exhibit a like efficiency, if efficiency is to be judged by the absence of complaint on the part of the recipients?

The disquieting increase in the number of claims for sickness and disablement benefit and the possibility of insufficient care in the issue of certificates of incapacity is again reviewed. All insurance practitioners have received a memorandum giving the results of certain investigations undertaken on the recommendation of the National Health Insurance Joint Committee, and the conclusions to which, in the view of the Department, these results point. Sir George Newman considers it quite clear that laxity of certification, though widespread, is by no means general—that there are, in fact, a very large number of practitioners to whose standard of certification exception could not reasonably be taken.

"What is necessary is that representative professional opinion should be brought to bear on those whose standard is defective, with a view to the removal of misconceptions and the development of a stronger sense of professional responsibility in this important matter."

The report adds that it is satisfactory to observe substantial signs of increased vigilance and care in the certification of incapacity.

As to the investigation of insurance prescribing, the steady decline of recent years in the average cost per prescription is taken as evidence of growing appreciation by insurance medical practitioners of the fact that it is the duty of the practitioner to refrain from ordering what is not reasonably necessary. During the year, although 1,185 practitioners were interviewed by medical officers of the Ministry, only 15 cases were referred for investigation by Panel Committees, in 13 of which it was found that unnecessary cost had been incurred. The *National Formulary* prepared by the Insurance Acts Committee appears to be finding general acceptance; only a comparatively small number of insurance areas now remain in which it has not been adopted.

The system of medical records has now obtained for ten years. The policy of the Department has been to secure compliance with the obligation rather by persuasion and steady pressure than by punitive action, and more than 70 per cent. of practitioners are keeping records satisfactorily. In 51 cases it was considered necessary for a warning letter on the subject to be sent by the Minister, and in 12 the defects were so marked as to necessitate withholding of remuneration.

"Apart from the fact that records are now very much better kept than in earlier years, it is worth mention that reports have repeatedly been received from the regional staff as to the increasing proportion of practitioners who are satisfied by experience of the value of the records, and state that they would be disposed to continue them, even though they were under no obligation to do so."

Other points of interest in this section are as follows: During 1930 the number of practitioners attending post-graduate courses under the facilities provided was 122, and the cost £3,542. There were 531,941 references to the regional medical staff, an increase of some 65,000 on the figure for 1929. Almost all were references by approved societies on the question of incapacity. The regional medical staff now consists of 5 divisional officers, 35 regional officers, and 43 deputies. The list, prepared and revised by the British Medical Association, of practitioners willing to advise on ophthalmic cases and prescribe spectacles where necessary (at a fee of one guinea) now includes 837 names in England and Wales. The sum of £400,000 was again allocated by approved societies and branches to ophthalmic benefit in 1930.

Reference will be made in a later issue to the parts of the report which deal with epidemiology, and with cancer and tuberculosis.

The Minister of Health and the Secretary of State for Scotland have jointly appointed a committee, with Lord Marley as chairman, "to examine the experience already gained in regard to the establishment of garden cities, and villages, and satellite towns, and to make recommendations as to (*a*) the steps, if any, which should be taken by the Government or local authorities to extend the provision of such garden cities, and villages, and satellite towns; (*b*) in particular how the location of industries in them can be stimulated; (*c*) the questions of finance and land government connected with their establishment; and (*d*) what further measures, if any, can and should be taken for securing that in the extension of existing towns industrial, residential, and other developments are properly correlated."

PSYCHIATRIC OUT-PATIENT CLINICS AT LONDON COUNTY COUNCIL GENERAL HOSPITALS

The facilities which exist at the Maudsley Hospital for diagnosis of neurotic and mental illnesses, and for the continued treatment of these conditions in its wards and out-patient department, have hitherto been less readily available to patients living in the northern districts of London than to those from parts south of the Thames. Initial attendance in the out-patient department has been essential, except in the case of patients recommended for admission by recognized consultants in nervous and mental disorders, and records of the source of patients show that the hospital is thought too remote for some. In order to increase accessibility of psychiatric diagnosis and treatment, the London County Council has recently decided to establish psychiatric out-patient clinics at each of three municipal general hospitals north of the river.

In view of the special relations of these clinics to the Maudsley Hospital (which are discussed below) the general supervision of the clinics has been assigned to the medical superintendent of that hospital, to whom all correspondence should be addressed. The physician in charge of each clinic will also be drawn from the Maudsley Hospital staff. With the latter, however, will be associated members of the staff of the London County mental hospitals. This medical staff will have the assistance for investigation and disposal of specially trained psychiatric social workers recently appointed by the Council.

While the Maudsley Hospital will continue to exercise unchanged all its previous functions in respect of patients living south of the Thames, the three other psychiatric clinics will serve as centres for consultation and selection more easily accessible to patients sent by practitioners in the northern areas. A short report and recommendation as to disposal will be sent to every doctor referring a patient to one of these clinics.

The essential condition of suitability for reference to one of these psychiatric clinics is likelihood of fitness for further treatment on a voluntary basis at the Maudsley Hospital or elsewhere. Among specially suitable conditions may be mentioned: (1) neurotic disturbances—for example, neurasthenia, hysteria, obsessional states and anxiety states; (2) mental or neurotic symptoms associated with well-defined physical disease. There are special facilities for treatment at the Maudsley Hospital of conditions belonging to both the above classes.

In determining suitability, severity of symptoms is perhaps of less importance than prognosis. But no useful purpose will be served by sending to the clinics patients of the following types:

1. Mentally defective patients of any grade.

2. Patients clearly requiring certification under the Lunacy Acts. These cases should as hitherto be referred to the relieving officer for admission to the observation ward.

3. Non-volitional patients suitable for being dealt with under the temporary treatment clauses of the Mental Treatment Act. These should also be referred to the observation wards.

While all facilities are available at the Maudsley Hospital for study and treatment of the abnormal child, they will not be available at the psychiatric out-patient clinics, and children should not be sent to these.

Patients should be accompanied by a relative or friend capable of furnishing a history and taking all necessary responsibilities.

It will greatly facilitate investigation if notice of the forthcoming attendance of any patient is sent in advance to the medical superintendent, Maudsley Hospital, Denmark Hill, S.E.5.

Mile End Hospital (Dr. Aubrey Lewis).—Monday, 2.30 p.m.; Thursday, 2.30 p.m. Stepney, Poplar, City of London, Bethnal Green, Hackney, Stoke Newington.

St. Mary Islington Hospital (Dr. Louis Minski).—Tuesday, 2.30 p.m.; Friday, 2.30 p.m. Hampstead, St. Pancras, St. Marylebone, Holborn, Islington, Finsbury, Shoreditch.

St. Charles's Hospital (Dr. E. W. Anderson).—Wednesday, 2.30 p.m.; Friday, 10 a.m. Hammersmith, Kensington, Paddington, Fulham, Chelsea, Westminster.

As indicated above, treatment (after the initial interviews necessary for complete diagnosis) will usually, owing to local exigencies of time and space, have to be carried out at the Maudsley Hospital, either in its wards or its out-patient department. Plans are under consideration for the expansion of the accommodation of the hospital to the extent likely to be necessary in order to meet increase of demand by the psychiatric clinics mentioned above.

The arrangements for continued out-patient treatment at the Maudsley Hospital have been much improved since the Mental Treatment Act legalized the necessary expenditure. By addition of special out-patient staff, not only has increase in frequency and in length of interviews been rendered feasible, but also continuity of treatment of a given patient by one psychotherapist has been more definitely ensured. All interviews after the preliminary ones are now by appointment at a definite time, and in the case of those in employment such appointments are made after working hours up to 10 p.m.

Ireland

Obstetrics and Gynaecology in Dublin

As in previous years the August issue of the *Irish Journal of Medical Science* is devoted mainly to the publication of reports of the three Dublin hospitals—namely, the Rotunda Hospital, the Coombe Lying-in Hospital, and the National Maternity Hospital. Previous reference has been made in these columns (August 8th, p. 270) to the satisfactory account which the Rotunda Hospital has again been able to render with regard to its progress in the twelve months ending October 31st, 1930. Dr. T. M. Healy, Master of the Coombe Lying-in Hospital, reports an increase of work in this institution during 1930, but observes that although the number of cases attending the pre-natal clinic has shown an increase of 80 per cent. over the 1929 figure, less than 25 per cent. of the deliveries conducted in the hospital relate to patients who have received pre-natal treatment. With a view to reducing puerperal morbidity a 2 per cent. solution of mercurochrome is injected into the vagina of all patients in labour in the hospital at intervals of six hours, and the Master concludes that fewer cases of minor infection have resulted since the introduction of this routine. In the treatment of established infection reliance is placed more upon general nursing principles than upon drugs, but good effects have been observed to follow the injection of anti-scarlatinal serum and the intravenous administration of quinine in association with anti-streptococcal serum. Results obtained in the treatment of septicaemia by the intravenous injection of serums have been disappointing. Moulding of the foetal head, good uterine pains, and the use of the Walcher position led to spontaneous birth in disproportion cases three times as often as operative intervention was necessitated. In all except one instance difficulty in delivery was most marked [illegible]

delivered in the wards of the National Maternity Hospital, and in the extern service 569 women were delivered. No death from puerperal sepsis was recorded in the hospital, and the morbidity rate was 3.2 per cent. Dr. P. T. McArdle, the Master, states that the number of cases of eclampsia continues to decrease steadily from year to year. He thinks that this is due possibly to better education of the expectant mother at the ante-natal dispensary of this institution. As regards placenta praevia, of which nine cases were recorded during the year, with no maternal deaths, he urges that immediate operation should follow the definite diagnosis of this condition, even though the initial haemorrhage is slight. Accidental haemorrhage is treated along conservative lines, shock being dealt with first, and care being taken not to rupture the membranes unless the patient is in strong labour with the os well dilated. Only six patients required the lower uterine Caesarean section, the condition present being disproportion due to contracted pelvis. Gratification is expressed that the indications for this operation continue to diminish each year, in consequence of the more prevalent induction of premature labour, and the employment of the Kielland forceps.

Vital Statistics for the Irish Free State

During the quarter ended June 30th, 15,175 births were registered in the Irish Free State, this number representing an annual birth rate of 20.5 per 1,000 of the estimated population. The equivalent figure for Northern Ireland was 22.5, for England and Wales 16.5, and for Scotland 20.0. The rate in the Irish Free State is 0.9 below the average (21.4) for the second quarters of the ten years 1921–30. Deaths registered during the quarter numbered 11,284, or an annual rate of 15.3 per 1,000. This rate is 0.1 below the average (15.4) for the second quarters of the preceding ten years. Of the deaths registered, 1,031, or 9.1 per cent., were those of infants under 1 year, the number of deaths of infants being equivalent to 68 per 1,000 births, compared with 52, 71, and 89 for the three previous quarters. Deaths from tuberculosis numbered 1,158, or a rate of 1.6 per 1,000, and deaths from cancer 753, or a rate of 1.02. The number of deaths from the principal epidemic diseases was higher by 20 than that for the second quarter of 1930, the mortality from measles being more than five times as high as the corresponding figure for last year, and 50 per cent. greater than the average for the period 1926 30. While the mortality from diphtheria also showed an increase as compared with the average figure for the five years, there was a considerable decrease in the number of deaths compared with 1930. Deaths from influenza represented a rate of 0.7 per 1,000, and deaths from puerperal conditions were equivalent to a rate of 3 9 per 1,000 registered births.

A New List of Dublin Hospitals for the Sweepstakes

Mercer's Hospital, Dublin, has made a formal application to the Hospitals' Committee to be allowed to participate in the proceeds of future sweepstakes. The Rotunda Hospital, Dublin, made a similar formal application some weeks ago. The Hospitals' Committee at its next meeting will consider these applications. In addition to the thirty-eight hospitals already accepted for the Manchester November Handicap sweepstakes as the hospitals among which the proceeds of the sweepstakes are to be distributed, the following six hospitals have been added to this list under the Public Charitable Hospitals (Amendment) Act, 1931: Our Lady of Lourdes Hospital, Kingstown; Peamount Sanatorium, county Dublin; Royal Victoria Eye and Ear Hospital, Dublin; St. Anne's Hospital, Rathmines, Dublin; St. Mary's Open Air Hospital, Finglas, county Dublin; and St. Joseph's Orthopaedic Hospital, Coole, county Westmeath. The Irish Hospital Trust states, in regard to reports in some English newspapers that sweepstakes tickets were being forged in England, that there is no foundation for the report.

Belfast Mental Hospital

The medical superintendent of the Belfast Mental Hospital draws attention in his report to the necessity for providing additional accommodation for the increase in the number of patients. He states that in the present economic circumstances it is very difficult to obtain money for public works not of a remunerative description; but the present overcrowded condition of the institution is most serious, and unless further accommodation is supplied there is grave danger that overcrowding may lead to unhygienic conditions of some of the buildings, as the number resident on December 31st, 1930, was some three hundred in excess of the normal. The care and treatment of recent cases is also hampered by this overcrowding. The statistical tables reveal that the patients admitted during the year numbered 393 (198 males and 195 females); discharged, 233 (113 males and 120 females); died, 165 (82 males and 83 females); number remaining on December 31st, 1,335 (689 males and 646 females). Compared with the previous year the admissions had decreased by 61, the discharges by 6, and the deaths by 37.

England and Wales

St. Thomas's Babies' Hostel

Not far from Lambeth Palace, and hidden among the somewhat decrepit masonry of the Kennington area, is an institution which is probably unknown to most. Described as "a dietetic hospital for sick babies and mothers," the St. Thomas's Babies' Hostel was, in pre-war days, a model day-nursery. During the war it served as a maxillo-facial hospital under the British Red Cross Society. Since then it has fulfilled many functions, and now it is a fully equipped institution primarily for the treatment of dietetic disturbances in mothers and babies. There is also a resident training school for nursery nurses, with a period of training which lasts a year. Arrangements are made for the treatment of infants up to the age of 3 years who may be suffering from nutritional disorders. The medical direction is from St. Thomas's Hospital. In the report for 1930 it is stated that very good results are obtained in cases in which both mother and baby are admitted for the purpose of restoration of breast milk; there are many other examples quoted, such as that of serious dietetic disturbances in a child who is already weaned, and who is admitted alone. It is emphasized that many of the children treated are of the "C3" class, but nearly all on discharge are strong and healthy, with every chance of growing up into useful citizens. One important point is that, on discharge, the diet for each child is chosen in accordance with the family purse. In many cases it is possible for the almoner to make some temporary arrangement for financial assistance until the child's gastric condition is more satisfactory. After discharge, the children are examined from time to time as out-patients. The report acknowledges with gratitude the gift of a new out-patient department where mothers can be examined, and where also lectures are given. It is hoped to extend this department in the future. There is nearly always a full complement of mothers and babies, 3 and 19 respectively. The out-patient attendances have reached a total of nearly

hundred, while the in-patient records show that during the year 33 mothers and 97 children were treated. The chief diseases were malnutrition, dyspepsia, and prematurity; there were 22 admissions for the re-establishment of breast feeding. Like most other institutions, St. Thomas's Babies' Hostel is in need of financial support. There is, roughly, a 33 per cent. deficiency every year, which can be made good only by charitable methods. This institution is one which contains both medical and social components, and there is great scope for voluntary social workers to act as assistants in the wards or to perform the "follow-up" part of the work which is so necessary for its success.

Street Lighting: A Leicester Experiment

A report issued by the Department of Scientific and Industrial Research (H.M. Stationery Office, 6d.) describes an experiment organized at Leicester in which the opinions of experts on a series of systems of street lighting are analysed and compared. This inquiry was a corollary to previous experiments at Sheffield. In the Sheffield investigation ten different street lighting installations were set up and a team of observers were asked to assess the glare effect of each; they were also asked to find the position at which glare was most noticeable, and to assess the visibility of objects on the roadway; and they were also given a test for visibility. The results at Sheffield appeared to indicate that there was a tendency to assess the degree of glare by the amount of discomfort experienced rather than by the reduction of visual sensitivity. The experiments at Leicester were directed to discovering whether the observers could form separate opinions regarding these two types of glare. Eight installations were set up of identical height and spacing, and arranged to give the same average illumination on the roadway. They were compared in pairs, two installations of any given pair being switched on alternately. The results show that the order in which the eight installations were placed by various observers was identical as regards estimates of the visibility of objects on the roadway, the reduction of ocular sensitivity, and discomfort glare. This common order was not, however, in good agreement with the reduction of ocular sensitivity calculated from laboratory investigations. It appears, therefore, that in estimating glare in street lighting observers are mainly influenced by the discomfort experienced. An installation in which all light was cut off at angles making less than about 10 degrees with the horizontal, so that only the nearest light source could be seen by an observer, was estimated by a large majority of the observers to have the highest visibility and to be least glaring. It was also judged to be, with one exception (an installation in which bare lamps were used), the least attractive. The opinion was expressed that the absence of distant light sources produced a depressing effect. The great majority of observers also found that the most attractive installation consisted simply of a large diffusing bowl. Freedom from glare was estimated to be high with this, but as regards visibility it was placed fifth among the eight installations compared.

The Leasowe Hospital for Children

During the twelve months ending December, 1930, 82.8 per cent. of all cases treated at the Liverpool Open-Air Hospital for Children, Leasowe, were discharged with the disease quiescent. These figures compare favourably with those for the previous years, which have ranged from 78.5 to 86.8 per cent. Dr. T. Hartley Martin, the senior medical officer, in his annual report remarks that tuberculous adenitis continues to respond satisfactorily to artificial light treatment, whether sinuses are present or not; similar good results have been obtained in tuberculous peritonitis, when intestinal tuberculosis is absent. No evidence was obtained that this treatment hastened recalcification in bone disease. Researches were also conducted into calcium metabolism, amyloid disease, and the excretion of tubercle bacilli from the kidneys. The average number of beds occupied continuously throughout the year by non-tuberculous cases was fourteen, the diseases being rickets, congenital and acquired deformities, and infantile and spastic paralysis. The work of the hospital as the central institution in connexion with the orthopaedic schemes in the locality continues to develop, and the associated clinics are increasing their activities. The orthopaedic workshops of the hospital provide the necessary splints, appliances, and boots.

Correspondence

RADIOLOGY AND THE RADIOLOGIST

SIR,—Your enlightened article in the *Journal* of August 29th contains the question, "Is the *x*-ray apparatus in future to be used, for example . . . as the stethoscope is used?" The answer of the future only the future can give. The answer of the present time is that, by some, the *x*-ray apparatus is now so used—that is, as a routine procedure by the clinician himself in all chest cases, whether pulmonary or cardiac.

X rays have many uses, including their use in the diagnosis of thoracic disease, in which it is one of the most important clinical methods available. The clinician, especially if a consultant as well, must surely feel obliged then to make constant use of such an important method of examination. Whether he produces and interprets his own radiograms, after acquiring the requisite skill, or sends his patient on to a radiologist to produce and interpret them, is of minor importance. Each clinician or consultant is free to decide this matter for himself. Some clinicians and consultants have found it a great advantage to their patients, and an added interest to themselves, to make radiography of the chest a routine method.

The alternative role prescribed for the consultant "behind the radiologist acting as a corrective" is not an indispensable role. The skilled radiologist so seldom needs a corrective, and the consultant may even "correct" the accurate and make it incorrect.

Whether the chest consultant should do his own radiology or not, will in the future be decided neither by the consultant nor by the radiologist, but by the practitioner who chooses one, or both, and then advises his patient, who pays one, or both.

The technical and other knowledge required by the radiologist is very great. Moreover, it has to be applied in such innumerable and complicated ways that there can only be one answer to the further question in your article, "Will a specialist branch still be required?" in radiology, and that answer is by universal agreement most assuredly in the affirmative. There must, however, be no monopoly.—I am, etc.,

London, W.1, Sept. 14th. A. HOPE GOSSE.

SIR,—May I, another who has followed the growth of radiology since its earliest days, support the views expressed by Dr. Stanley Melville in his letter in the *Journal* of September 12th. It is right that the clinician should use *x*-ray diagnosis in his practice; a moderate amount of training should enable him to do so successfully in a variety of conditions. But when it comes to diseases of the chest, long and constant experience is needed to

avoid mistakes in interpretation ; and this applies even more forcibly to the gastro-intestinal system. I am strongly of opinion (having witnessed many instances) that none but a specialist in radiology is competent to interpret correctly the infinite variety of appearances presented on the screen—and on films—during the passage of bismuth through the alimentary canal, and of a barium enema through the large intestine.—I am, etc.,

London, W.1, Sept. 18th.

STOMATITIS OF DENTAL ORIGIN

SIR,—May I point out what I think is a serious fallacy in Mr. Bedford Russell's valuable paper on sore throats of other than tonsillar origin in your issue of September 12th. He says:

"While on the subject of what may be termed this 'watch-dog' function of the fauces, it is illuminating to remark upon the absence of this property in the buccal mucous membrane. This mucosa takes little or no notice of dental sepsis, at a time when the fauces may be responding most actively to this very same insult."

My observations lead me to an exactly opposite conclusion—the buccal mucous membrane quickly and constantly resents the presence of dental sepsis. Most commonly the result is of a "chronic" inflammatory nature, so often generalized to the whole mouth that I have given it the name of "chronic generalized septic stomatitis." Further, this condition is itself so common that what is pathological is currently passed as normal, and what is normal is very seldom to be seen.—I am, etc.,

J. G. TURNER, F.R.C.S., L.D.S.

London, W.1, Sept. 18th.

PROSTATECTOMY OR DRAINAGE

SIR,—In your issue of to-day I accidentally discovered my name under the above heading. I have always advocated prevention in preference to cure, but why Dr. Neve should have saddled me with two alternatives which are neither prevention nor cure, I know not. If elderly men were wise enough not to get large prostates there would be no necessity for either alternative. In an article in the *Practitioner* (June, 1921) on "Hyper- and hypothyroidism: causation, prevention, and treatment," I said that an enlarged prostate is a fertile field for surgeons, who had better make hay while the sun shines, for old gentlemen may become sufficiently enlightened not to have enlarged prostates. In fact, I think the beginning of the slump is in sight. A big prostate is a very troublesome companion, and he who is so ill advised as to get one had better get rid of it if the only alternative be a catheter life.

I have been interested in the prevention of an enlarged prostate since 1893, when Dr. J. W. White of Philadelphia conceived the idea that an enlarged prostate was analogous to fibromyomata of the uterus ; and, as the latter were apt to atrophy, or become quiescent after the menopause, and after oöphorectomy, so he thought that the removal of one or two testicles might have a similar beneficial effect in the male. He had a series of experiments carried out on dogs, and he found, as he anticipated, that after castration the prostate atrophied. He then operated, more or less successfully, on many human subjects. This treatment was introduced to this country by the late Reginald Harrison, but whether he ever performed the operation or not I am not certain. At any rate, it never caught on to any extent. Dr. White's conclusions were logically drawn, but as they were based on false premisses his treatment was not a success, and soon died a natural death.

In 1894 I saw on several occasions, with the late Dr. Joseph Matthews, a gentleman who was suffering from an enlarged prostate and cystitis. He had previously been seen by two surgeons and the late Dr. William Carter. Extirpation of the prostate had not then come to stay. I drew their attention to White's operation, which, apparently, did not meet with the approval of the patient, possibly because he was married to a young lady. At any rate, my services were not further requisitioned. A few months later I met the patient out at dinner. He condescendingly told me that medical men did not know their business, that he had sacked the lot, placed himself under the care of an electrician, and he was now quite well. I congratulated him on the result, but did not inquire as to how it had been attained ; however, I think I profited by the lesson. So far as the prostate was concerned, it gave rise to no further trouble to the end of the chapter. I did not see him again professionally till September, 1904, when he was dying from uraemia.

An enlarged prostate is a sign of degeneracy, and its mere removal will not arrest the degeneracy which is associated with defective action of the thyroid, the gonads, and increased storage of calcium. Many of these old gentlemen have an excellent poker-face, but they lack the intelligence behind to play the game, and when they try to smile or laugh it does not require a cartoonist to depict the derelict. The remedies are iodine, thyroid, and decalcifying agents.

In my address at the Annual Meeting of the Canadian Medical Association at Montreal in 1911, on "Preventive medicine: the medicine of the future" (*British Medical Journal*, June 10th, 1911), I dealt with this subject. A friend who read my manuscript wished me to omit the part dealing with the prostate, as he said my views were not established. I replied that to me they were facts, and "Facts are chiels that winna ding, and downa be disputed." I was not going to wait for anyone else to make the discovery before my publication. However, there seems not to have been any hurry ; prevention lags behind, and operations go on.—I am, etc.,

JAMES BARR.

Hindhead, Sept. 19th.

SIR,—Dr. Ernest Neve's remarks (September 19th, p. 550) indicate in a few words the difficult problem the general practitioner is expected to solve in advising treatment for prostatic obstruction. His responsibilities are made worse because it happens so often that not till the patient is overtaken by the crisis of acute retention will he accept operative treatment. This predicament is usually avoidable, for the reason that during the stage of chronic retention most patients have had the advice of their medical attendant to have something done while the general health was still good.

Suprapubic drainage in those cases of chronic retention which have ended in complete retention will be successful in the great majority, if it is preceded by an *in-dwelling* catheter, which provides at first a slow, regular, and intermittent relief of the retention, and subsequently continuous drainage. In this way the general health can be improved so that operative risk is slight. Mortality from cystotomy is considerable or slight according to the amount of pre-operative preparation and the nature of the operative technique employed. Results amply repay earnest attention to these facts.

It occasionally happens that the renal damage is too severe for the patient to show any improvement from an in-dwelling catheter, and he continues to go downhill. A true appreciation of the course the case is taking will prevent a cystotomy which will only hasten the patient's end. Once through the cystotomy, prostatectomy, which is contemplated, can be delayed until such time as there is little risk from operation. Or the patient may re-

with his suprapubic drain permanently My experience with patients wearing the permanent suprapubic apparatus is that there is no difficulty in preventing leakage round the suprapubic tube provided the Jacques catheter is not fitted before the fistula has a firm wall of fibrous tissue It is better to wait two or three months for this In the meantime, a self-retaining suprapubic tube, if correctly chosen and fitted, will prevent leakage

With proper attention these patients remain in a state of comfort for so long as the bladder can be kept free of signs of excessive irritation But it has been my experience that in spite of every care these signs develop *within one or two years in a certain number of cases*, generally because of calculous deposit in the bladder Fortunately, at this time, the majority of the patients have improved so much that prostatectomy is undertaken and successfully borne, even when in the first instance the patient's general condition gave no hope that this would ever be possible —I am, etc,

H P WINSBURY WHITE F R C S

London, W 1, Sept 20th

BREECH DELIVERY

SIR,—The opinions recently expressed on the subject of foetal mortality in breech delivery do not seem to have made the position any clearer, and no statistical data have been presented to show that there is any decrease in the foetal mortality following slow delivery in order to avoid intracranial haemorrhage, as opposed to more rapid delivery to avoid inhalation asphyxia Is there not a danger of the pendulum swinging too far in favour of slow delivery?

If an intracranial haemorrhage is found in a stillborn child, is there any justification for stating that the haemorrhage was necessarily the cause of the stillbirth? It is agreed that intracranial haemorrhage in the newborn child occurs with comparative frequency, and need not necessarily be fatal If this is so, is the pathologist correct in saying that a small haemorrhage found, often with difficulty, at necropsy is the cause of the death, and that death was not due to de oxygenation from one of the several other causes? It seems that asphyxia as the cause of death is only accepted in those cases in which nothing abnormal is found post mortem In the present state of our knowledge, or rather ignorance, of the physiology of the medulla and of the circulation about the time of birth, the clinical conditions known as "asphyxia pallida" and "asphyxia livida" can have no real diagnostic significance

I certainly must agree with Dr Cook that insufflation of fluid into the upper air passages is more than a possibility, particularly if strings of mucus are included The presence of mucus in the upper air passages can and does cause reflex inhibition of respiration, and the removal of mucus from the throat is by far the most important treatment of asphyxia in the newborn

The following method of delivery reduces the risk of death from asphyxia to a minimum, while, at the same time, it does not increase the risk of intracranial haemorrhage After the birth of the buttocks, delivery is aided by suprapubic pressure and by means of a finger in the mouth As soon as the mouth is judged to be within reach of a full sized Sims speculum, this is inserted by an assistant, and from this time onwards the child can, and frequently does, breathe Delivery is completed with the utmost gentleness Traction is never made through the neck from the shoulders

Mr Bourne has aptly said that the management of a breech delivery is like steering a ship between two rocks—intracranial haemorrhage and asphyxia My object is to present asphyxia as a very dangerous rock. It is at present dwarfed by the magnified crags of intracranial haemorrhage, and is submerged by the tide of high medical opinion, although submerged, let it not be uncharted —I am, etc,

J SHIRLEY CALLCUTT

Maternity Hospital, Kingsbury, N W 9, Sept 14th

THE CAUSE OF TORTICOLLIS

SIR,—In the *Journal* of September 12th there is a surprising letter from Mr Paul Bernard Roth on the cause of torticollis He states that his own view is that "the 'sterno mastoid tumour' is due to a tear, not of a normal muscle, but of a previously contracted one" He apparently assumes that this view is correct, for he inquires whether 'the same cause, whatever it is may produce the breech presentation and the shortened muscle," and later speaks of the child with the ruptured *sterno mastoid muscle*'

It would greatly interest me to know what evidence he has that there is a rupture of muscle at all—shortened or unshortened If a muscle is torn, surely the ends separate, leaving a gap, surely, also, the muscle is subsequently longer or potentially longer with a weak scar tissue intersection at the site of tear There are none of these features in a case of torticollis, either in the early or late stages On the other hand, one finds that often at birth very little abnormality can be detected, and the "tumour" develops in a few days as a hard, round mass fading into the rest of the muscle At this time the muscle is shorter, and the head consequently tilted and turned in the typical manner After a few weeks treatment by stretching and massage the swelling disappears and the deformity is non apparent, though a palpable hardness may remain for some months In four or five years the deformity recurs as the typical wry neck so commonly encountered There is never at any time any suggestion of solution of continuity of the muscle

It has been my view and teaching for many years that the condition is an ischaemia exactly comparable with that of the flexors of the forearm I have thought that during labour the muscle is "pinched" and in a few days becomes swollen Later, fibrosis develops, which is for a time immaterial, but as growth proceeds the muscle does not grow *pari passu* with the bones, and the relative "shortening" becomes apparent

This view was strengthened by the work of D Stewart Middleton, published in the *British Journal of Surgery* (October, 1930, xviii, 188), and anyone interested in the subject would be well advised to read this excellent article, which produces pathological support for clinical observations —I am, etc,

Liverpool, Sept 14th BRYAN MCFARLAND

CONVULSIONS DURING ETHER ANAESTHESIA

SIR,—Dr Bashall, commenting upon the case I reported in your issue of August 29th states that oxygen seems to be the crux of the whole situation If oxygen could be proved to be a constant factor in all the cases reported one might be impressed, but in many cases it appears not to have been employed till after the onset of the convulsions, and in one case it is definitely stated not to have been used at all

As to the use of Shipway's apparatus with oxygen, I have employed this method for about fourteen years upon, I think, a few thousand cases This "careless anaesthesia should surely by now have yielded a much richer crop than the solitary case I have been able to report —I am, etc,

Burnley, Sept 14th JAMES HEWORTH.

INJURY AND SPORT

SIR,—My attention has been called to the fact that Dr. Heald, in a recently published book, in referring to treatment by graduated contraction of muscles, electrically provoked, writes:

"The credit of introducing muscle movements and re-education is chiefly due to Mr. Rowley Bristow, and the apparatus is therefore often called by his name."

As this and similar statements have appeared in various publications, I feel obliged to write and disclaim any responsibility as the introducer or inventor of this method. In a small book, entitled *The Treatment of Muscle and Joint Injuries*, which I wrote in 1917, I stated:

A brief account of this method of treatment was published in a paper entitled "The treatment of muscular and joint injuries by graduated contraction," in the *Lancet* in 1912, by Dr. Morton Smart and myself, and he was the first medical man to systematize and work out the particular method hereinafter described of dealing with both acute and chronic joint injury.

Dr. Morton Smart, in 1923, read a paper at the Electro-Therapeutic Section of the Royal Society of Medicine, and gave a demonstration with the new coil which he was using. In the subsequent discussion I again disclaimed any connexion with the invention of the coil. I explained that it had been my task to introduce it into the special military hospitals and to demonstrate its effect in the treatment of muscle injury and muscle insufficiency, and that my knowledge of the coil and its working came direct from Dr. Smart.—I am, etc.,

London, W., Sept. 18th. W. ROWLEY BRISTOW.

THE DIABETIC ACUTE ABDOMEN

SIR,—In the account of the typical case of this condition recorded in the *Journal* of September 19th by Drs. Lawrence, Millman, and Pilkington, the fact that vomiting preceded the onset of pain is not stressed in the differential diagnosis from the true acute abdomen. In both conditions pain, vomiting, and a high leucocytosis are the rule; but in the true acute abdomen the pain occurs before the vomiting, whereas in the pseudo-acute abdomen of the diabetic the vomiting precedes the pain.—I am, etc.,

London, W.1, Sept. 21st J. A. CAIRNS FORSYTH.

HUNGER PAINS AND PRESERVATIVES

SIR,—The query that Dr. A. P. Luff raises I am unable to answer. A few years ago, desirous of knowing the preservatives that were added to food, I wrote to the Ministry of Health, but apart from an acknowledgement of my letter I received no other communication. But my indigestion is provoked by the articles to which Dr Luff states sulphur dioxide is added, and to find that beer is thus treated is interesting, for, whilst my friends assured me that this beverage was pure, I noticed that a glass of it induced hunger pains. As similar effects result from sweetened mineral drinks I now take water. The preservative that is added to butter brings on the symptoms, for, whilst always buying the best, my indigestion did not cease until butter was obtained direct from a farm. Of it I now eat much, whereas formerly I partook of it sparingly, assuming my stomach could not deal with this form of fat. Not the fat, but what was added was the offender. My unfamiliarity with the measures adopted for preserving perishable food is shared by many medical men, and until the label that describes the article gives the preservatives it contains and its percentage our unenlightenment will continue.—I am, etc.,

London, W., Sept. 10th. J. FORREST.

SHORTENING OF AN ELONGATED UVULA FOR THE CURE OF COUGH

SIR,—I wish to confirm Sir James Dundas-Grant's assertion (*British Medical Journal*, September 19th, p. 549) regarding the success of curing a cough by cutting off a piece of lengthened uvula. The cases calling for this operation are those in which the cough is troublesome when the patient is lying on his back, when there are no symptoms or signs of intrathoracic or laryngeal trouble, and when the uvula is unusually long.—I am, etc.,

W. M. FELDMAN, M.D., M.R.C.P.

London, W.1, Sept. 19th.

Obituary

SIR W. R. CROOKE-LAWLESS, K.C.V.O., M.D.

Surgeon Lieutenant-Colonel (ret).

Surgeon Lieut.-Col. Sir Warren Rowland Crooke-Lawless, K.C.V.O., C.B., C.I.E., C.B.E., died at Folkestone on September 14th, aged 68. He was born at Macroom, County Cork, the son of Dr. W. Crooke of that town, on January 9th, 1863, graduated as M.D. and M.Ch. in the Royal University, Ireland, in 1884, and entered the Army as surgeon on January 30th, 1886. He was transferred to the Scots Guards as surgeon major on April 2nd, 1898, and exchanged into the Coldstream Guards on November 9th of the same year. He was promoted to surgeon lieutenant-colonel for services in the South African war on August 22nd, 1902, and retired on March 15th, 1911. When the war of 1914 broke out he was recalled from the Reserve of Officers to the active list, and served throughout the war. From 1920 to 1924 he was house governor and medical superintendent of the King Edward VII Convalescent Home for Officers at Osborne, Isle of Wight. He served with the Coldstreams throughout the South African war, 1899-1902, when he took part in the advance on Kimberley, including actions at Belmont, Enslin, Modder River, and Magersfontein; in operations in the Orange Free State, including actions at Poplar Grove, Dreifontein, Vet River, and Zand River; and in the Transvaal, with actions at Pretoria, Johannesburg, and Diamond Hill; was mentioned in dispatches in the *London Gazette* of September 10th, 1901, and July 29th, 1902, and received the Queen's medal with six clasps and the King's medal with two clasps, as well as a special promotion.

During the war of 1914–18 he was six times mentioned in dispatches, and received the C.B. and C.B.E. in 1917. He served as surgeon to Lord Minto, Viceroy of India, from 1905 to 1910, and received the C.I.E. in 1907, and a knighthood in 1910; he was made K.C.V.O. on retiring from Osborne in 1924. He was also an LL.D., a D.L., Lieutenant for County Cork, and a Knight of Grace of St. John of Jerusalem. In 1894 he married Emily Anne, daughter of Mr. C. E. Lawless, and took her surname; his wife died in 1927.

SAMUEL RUTHERFORD MACPHAIL, M.D.

The death took place on September 12th, at his residence in Dryden Place, Edinburgh, of Dr. S. R. Macphail, who was for many years medical superintendent of the Saughtonhall Mental Hospital, Polton, Midlothian. He had been in poor health for some time before his death.

Born in 1857 at Isle Ornsay, Skye, Samuel Rutherford Macphail was educated at Daniel Stewart's College, Edinburgh, and graduated M.B., C.M. at the University of Edinburgh in 1878, and took the M.D. degree four years later. Immediately after graduation he decided to devote himself to mental diseases, and he gained the medical prize of the Medico-Psychological Association in the

He acted successively as assistant medical superintendent of the Cumberland and Westmorland Asylum, medical superintendent of Derby Mental Hospital, and medical superintendent of New Saughtonhall Mental Hospital, near Edinburgh. Along with Dr. W. A. Macnaughton, lately M.O.H. Kincardineshire, he founded the Caledonian Medical Society, which recently celebrated its jubilee, and of which he was for a time president and also acted as secretary. He took a deep interest in the work of this society, which exists as a bond of union between medical men of Scottish birth or associations, and he was mainly responsible for making the arrangements in connexion with its annual meetings. The society publishes quarterly the *Caledonian Medical Journal*, and in that periodical Dr. Macphail also took a great interest. Dr Macphail was the author of contributions to medical literature dealing with mental diseases, such as "Clinical observations on the blood of the insane," which was a prize essay of the Medico-Psychological Association, "A case of Addison's disease associated with insanity," in the *Journal of Mental Science* (1885); and "The mental equation in bodily disease," in the *Quarterly Journal of Medicine* (1897).

A funeral service was held in St. Cuthbert's Parish Church, Edinburgh, on September 16th, and the interment took place at Lasswade Churchyard, attended by a large number of members of the medical profession.

Universities and Colleges

UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

A course of twenty lectures on the history and practice of medical industrial psychology will be given during October, November, and December by Millais Culpin, M.D., F.R.C.S., professor of medical industrial psychology in the University of London; Eric Farmer, M.A., lecturer on medical industrial psychology, Major Greenwood, D.Sc., F.R.C.P., F.R.S. professor of epidemiology and vital statistics, and May Smith, M.A., D.Sc., lecturer on medical industrial psychology. At the first of the series, on October 1st, which will be Professor Culpin's inaugural lecture, the chair will be taken by Air Vice-Marshal Sir David Munro, K.C.B. This course is designed to meet the requirements of students for the Academic Diploma in Psychology of the University of London, and also of students for the degree of Ph.D. in medicine (non-clinical subjects). The lectures will be given on each occasion at 5 p.m., at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1. The fee for the complete course, in the case of persons not members of the School's D.P.H. class, will be £2 2s. Admission to the introductory lecture will be free.

The Services

HONORARY PHYSICIAN TO THE KING

Colonel L. D. Bailey, *M.C.*, T.D., Assistant Director Medical Services 47th (2nd London) Division, T.A., has been appointed Honorary Physician to the King vice Colonel J. G. Martin, T.D. (*ret.*).

EFFICIENCY DECORATION

The King has conferred the Efficiency Decoration upon Major John Samuel Hudson, R.A.M.C. (T.A.), under the terms of the Royal Warrant dated September 23rd, 1930.

TERRITORIAL DECORATION

The Territorial Decoration has been conferred upon Lieut.-Colonel Josiah Walker, *M.C.*, *R.A.M.C.* (*T.A.*), under the terms of the Royal Warrant of October 13th, 1920.

NORTH PERSIAN FORCES MEMORIAL MEDAL

The North Persian Forces Memorial Medal for 1930 has been awarded to Dr. T. F. Anderson, Colonial Medical Services, for his paper on "A report on an investigation of health conditions on farms in the Trans-Nzoia, with special reference to malaria," published in the *Kenya and East African Medical Journal* for January, 1930. The medal is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding twelve months by a medical officer of under twelve years' service of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or the Colonial Medical Service, *provided that the* Memorial Committee consider that any paper published has attained a standard of merit justifying the award.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

In the House of Commons this week the Chancellor of the Exchequer (Mr SNOWDEN) explained that it was necessary to make sterling currency temporarily inconvertible. A Bill for this purpose was passed forthwith by both Houses and became law. Later in the week the House of Commons discussed the Finance Bill on second reading and the Economy Bill in committee. A proposal that the latter Bill should be withdrawn, owing to the departure from the gold standard, was made from the Opposition side, but was not entertained by the Government. Mr MACDONALD announced however, that the "cuts" in the salaries of teachers, police, and the defence services would be limited to 10 per cent.

National Economy Bill

During a discussion, on September 18th, of a Government resolution authorizing the payment or diversion of money under the National Economy Bill, Mr CHAMBERLAIN (Minister of Health) said that in the case of doctors and chemists the Government proposed to reduce their remuneration by approximately one-ninth. He would like to pay a tribute of admiration and gratitude to the doctors and the chemists for the spirit in which they received this cut. They said at once that, treating this deduction not as a readjustment of their remuneration on its merits but simply as a call made upon them to contribute to the national need, on that basis they would readily pay their share. That was a very fine example, and the Government was grateful to them. The result of that action would be that in a full year there would be forthcoming *£850,000 by way of deduction from the doctors remuneration*, and £120,000 by way of deduction from the chemists' remuneration, *and those sums would be appropriations in-aid* of the Exchequer payments in the cost of administration of national health insurance.

Mr PETHICK LAWRENCE, speaking for the Labour Opposition, said they also should tender to the doctors and chemists their thanks for these sacrifices.

Dr FREMANTLE said there were 15,000 panel practitioners, practically all of whom were represented in the British Medical Association. Their spokesmen had discussed the position frankly with the Minister of Health. They had shown that, in the ordinary course of events, their contract with the State was binding, and any proposed alteration should have been submitted to a court of arbitration. The representatives of the profession took the line that, in accepting a cut of 11½ per cent., they made a contribution to the financial position in the present emergency without prejudice to the necessity of a revision of the rates of pay in the ordinary way. When that time came much would be said about the increased demands made on panel doctors for services for which a capitation rate of 9s. was fixed some few years ago. He went on to point out that, under the new Finance Bill, panel practitioners would also have to pay additional income tax and an extra petrol tax. This had brought no change in their attitude. They recognized they must suffer with the rest of the community. He reminded the House that the panel doctor lived on a very small margin, and that he was not a whole-time employee of the State. The chemists took the same patriotic line.

Mr CAMPBELL STEPHEN said a ballot of medical men would show they were as indignant as any other section of the community.

Mr LLEWELLYN JONES said the cut in the fee to be paid to medical men was more than 11½ per cent., and reduced the fee per panel patient nearly to the figure arrived at by agreement in January, 1913. At least 30 per cent. of the payments received by medical men represented the expenses

of their practices, so the real cut was 18 or even 20 per cent. He trusted it would not mean detriment to the medical service of the country.

The resolution was carried by 219 to 155. Subsequently the House arranged to discuss the economies in national health insurance on September 25th.

Economy by Local Authorities

Mr CHAMBERLAIN, when answering questions by Dr. Marion Phillips and Mr. Thomas Lewis on September 17th, said his circular urging local authorities to seek economies did not supersede the circular of December, 1930, urging them to extend work for saving maternal and infant life. It would be for each local authority to consider whether further development of maternity services was required at present. The maternity scheme which was considered by the Committee on National Expenditure could not in any event come into effect for a considerable period.

Medical News

The annual dinner of past and present students of University College Hospital will be held at the Hotel Victoria, Northumberland Avenue, W.C., on Friday, October 16th, at 7.30 p.m., with Dr. H. J. Shirley in the chair. The annual dinner of past and present women students of the hospital will be held at the Piccadilly Hotel on the same evening at 7.45 o'clock.

The annual prize distribution at Charing Cross Hospital Medical School will be held in the council room of the hospital on Friday, October 2nd. The chair will be taken by Mr. George Verity at 4.15 p.m. and the prizes will be presented by Sir George Newman. On Saturday and Sunday, October 3rd and 4th, a week-end post-graduate course, restricted to past students of the hospital, will be held. On Saturday, October 3rd, the annual dinner of past and present students will be held at the Royal Adelaide Gallery, King William Street, W.C., at 8 p.m., under the presidency of Dr. J. M. H. MacLeod.

The inaugural address at the Westminster Hospital Medical School will be given by Sir Henry Hadow, in the board room of the hospital, on Thursday, October 1st, at 3 p.m., with Lieut.-Colonel H. C. Bulkeley in the chair.

The new session at the London (Royal Free Hospital) School of Medicine for Women will open on Thursday, October 1st, at 3 p.m., when the Right Hon. Sir John Simon will present the prizes and deliver an address.

Lord Dawson of Penn, President of the Royal College of Physicians, will open the new sanatorium at Epsom College on the afternoon of Saturday, October 3rd. Guests will assemble in a marquee at 2.45, and at 3 o'clock Lord Dawson will give an address, which will be followed by inspection of the sanatorium and tea in Big School.

At the meeting of the St Pancras Division to be held in the British Medical Association's House, Tavistock Square, on Tuesday, October 13th, at 9 p.m., Lord Moynihan will give an address entitled "Ancient medicine and surgery."

Professor Arthur Hall will deliver the Schorstein Lecture on "Chronic epidemic encephalitis," at the London Hospital Medical College, on Thursday, October 15th, at 4.15 p.m.

The second winter session of the Hampstead General and North-West London Hospital Post-Graduate School, Haverstock Hill, N.W.3, will open on Wednesday, October 7th, at 4 p.m., when Sir William Willcox will discuss diabetes, its causation and treatment, with special reference to toxic causes. The course will be continued on successive Wednesdays at 4 p.m., terminating on December 16th.

The annual dinner of the Surgical Instrument Manufacturers' Association will be held at the Holborn Restaurant on Friday, October 9th, when the principal guests will be Mr. T. P. Dunhill, Mr. A. R. Melhuish, and Mr. L. Ferris-Scott.

The Fellowship of Medicine and Post-Graduate Medical Association announces the following courses: medicine, surgery, and specialties at the Metropolitan Hospital, Kingsland Road, E., from September 28th to October 10th, occupying the whole of each day; fee £3 3s., or £2 2s. for one week only. A similar course at the Prince of Wales's Hospital, Tottenham, from October 12th to 24th; fee £5 5s., or £3 3s. for one week. A course of lectures for the M.R.C.P. in the evenings, at 8.30, at the Medical Society of London, 11, Chandos Street, Cavendish Square, on Mondays and Wednesdays, beginning October 5th; fee £6 6s. for eighteen lectures, or 10s. 6d. per lecture, payable at the lecture room. Two special eye demonstrations will also be given, fee 10s. 6d. each; early application for these is essential. Diseases of the throat, nose, and ear at the Central London Throat, Nose and Ear Hospital, Gray's Inn Road, occupying the whole of each day, from October 5th to October 31st, and including a clinical course, fee £5 5s.; a pathology class, fee £5 5s. (limited); a peroral endoscopy class, fee £6 6s. (limited); and an operative class, fee £7 7s. (limited). Tropical medicine at the Hospital for Tropical Diseases, 25, Gordon Street, from October 5th to 24th, occupying the whole of each day; fee £8 8s. A course in diseases of the skin will be given at St. John's Hospital, Leicester Square, from October 12th to November 7th. Gynaecology will be the subject of a course at the Chelsea Hospital for Women, October 12th to 24th, fee £5 5s., and paediatrics at the Hospital for Sick Children from October 19th to 31st, fee £5 5s. As the latter course will not be held unless ten post-graduates enter for it, early application is desirable. A course in cardiology will be held at the National Heart Hospital from October 12th to 24th, fee £7 7s. Copies of syllabuses of all courses may be obtained from the Fellowship of Medicine, 1, Wimpole Street, W.1, also syllabuses of the series of free lectures and demonstrations for October, November, and December.

A new course of post-graduate lectures and demonstrations by the honorary staff of the Manchester Royal Infirmary will open on September 29th, when Dr. W. R. Douglas will lecture on surgery of the common bile duct. The lectures will be continued on succeeding Tuesdays until December 15th, with the exception of November 10th, when Professor W. Blair Bell (Liverpool) will deliver the Manchester Lloyd Roberts Lecture at St. Mary's Hospitals, Whitworth Street, Manchester, at 4.15 p.m. Demonstrations will be given on Fridays, from October 2nd onwards. The lectures and demonstrations will begin at 4.15 p.m.

A post-graduate course for former students will be held at the London Hospital Medical College from October 14th to 17th inclusive. It includes four morning sessions and three afternoon sessions, and an evening demonstration of methods of anaesthesia. The annual old students' dinner will be held on Thursday, October 15th, at the Trocadero, at 7.30 for 8 p.m. Luncheons can be obtained in the College dining hall, and tea will be provided in the committee room.

Under the auspices of the Tavistock Square Clinic for Functional Nervous Disorders, a course of eight lectures on "'Nerves'—ancient and modern" will be given at the Friends House, Euston Road, N.W. (opposite Euston Station), on Mondays, beginning October 12th, at 6 p.m., by Professor Millais Culpin. Fees for the course, £1 1s. Tickets must be obtained in advance from the honorary lecture secretary, 51, Tavistock Square, W.C.1.

A course in venereal diseases will be held at the municipal clinic of the Salford Public Health Department, consisting of fifteen lectures and demonstrations in modern methods in diagnosis and treatment; fee, £1 1s. The first lecture will take place on October 8th, at 7 p.m. This course of lectures qualifies for the University certificate, for which there is a fee of £2 2s., payable in advance to the bursar at the University. Those who intend to take the course are requested to send their names to the venereal diseases officer not later than October 1st, so that the necessary arrangements can be made.

The fifth Spanish Congress of Paediatrics will be held at Granada from October 19th to 23rd, under the presidency of *Professor Suñer Ordoñez*

Mr. E D Simon, M P, has been appointed Parliamentary Secretary to the Ministry of Health

The Faraday Centenary Number of the *Times*, published on September 21st, contains a series of illustrated articles reviewing Faraday's life and work, and surveying the practical application in industry of his researches and discoveries The story of his career is told by Commander Rollo Appleyard, and a psychological study is contributed by Professor Wilhelm Ostwald Lord Rutherford discusses Faraday's methods under the heading of "Prince of experimenters," while Sir William Bragg recounts the early deductions that led up to the epoch making experiment on August 29th, 1831 In another article Sir William shows how the foundation of the Royal Institution provided Faraday with the means for expressing his genius Sir J J Thomson writes on the link between Faraday and Maxwell, and the achievements of Faraday's successors are outlined by Professor W M Thornton The modern applications of Faraday's researches are dealt with by a distinguished list of authorities, including the Marchese Marconi, who traces the science of wireless communication to its source in Faraday's laboratory

In connexion with the centenary meeting of the British Association and the Faraday celebrations of the Royal Institution, a reception was held at the National Physical Laboratory, Teddington, by the director, Sir Joseph Petavel, on the afternoon of Thursday, September 24th, when the scientific work of the laboratory was demonstrated

The National Council for Mental Hygiene has arranged the following series of lecture-discussions to be held in the Lecture Room of the Medical Society of London, 11, Chandos Street, Cavendish Square, W, on Thursdays at 5 15 p m . October 22nd, prevention and treatment of nervous breakdown, Dr Helen Boyle, October 29th, sex education, Dr Israel Feldman, November 12th, crime and punishment, Dr Letitia Fairfield, November 19th, the mind of a child, Dr William Moodie, November 26th, marriage and parenthood, Dr Doris Odlum, December 10th, psycho analysis, Dr Ernest Jones Tickets price 1s 6d each, or 7s 6d for the course, may be had from the secretary, National Council for Mental Hygiene, 78, Chandos House, Palmer Street, S W 1, or at the doors

Under the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy, a course of post-graduate lectures on maternity and child welfare will be given at the Infants Hospital, Vincent Square, Westminster, on Mondays, from October 5th to December 7th, from 6 30 to 7 30 p m This course, which is arranged for health visitors, nurses, midwives, superintendents of infant welfare centres, and others interested, is part of the preparation for the post-graduate certificate of the National Association, and deals with such subjects as the psychology and education of the expectant mother, nutrition in infants and pre-school children, the teaching of mothercraft, and child guidance The fee for the course is 7s 6d , and further information is obtainable from Miss M E Richards, at the offices of the National Association, 117, Piccadilly, W 1 The National Society of Day Nurseries has arranged for a course of elementary lectures on infant care, to be given at Carnegie House, 117, Piccadilly, on Thursdays, from October 8th to December 10th, from 7 30 to 8 30 p m The course is intended for crèche nurses and probationers, and the fee for it is 10s A detailed syllabus may be obtained from Miss Maddock, at the offices of the National Society, 117, Piccadilly

A vacancy has arisen at Epsom College for a Salomons entrance scholarship of £50 a year Candidates must be sons of legally qualified members of the medical profession either living or deceased, only those may apply who were over 11 years and under 14 years of age on January 1st last The regulations provide that the candidate must show an adequate standard of education for his age, and that his financial condition is such as to make it impossible to obtain an education at the College without the help of the scholarship Applications must be delivered by the morning of September 30th to the secretary of the College, 49, Bedford Square, W C 1, from whom the requisite forms can be obtained.

An outbreak of forty-nine cases of enteric fever has recently occurred in Basel So far only one case has proved fatal

A severe epidemic of dengue has broken out in the island of Skyros in the Aegean

Dr Agnes Blum of the Kaiser Wilhelm Institute for Biology has been awarded the Leibnitz silver medal for her work on alcohol and heredity by the Prussian Academy of Sciences

Dr. Leriche, professor of clinical surgery at Strasbourg University, has been appointed professor of external pathology of the Lyons Medical Faculty

According to a law recently passed in Rumania, houses of prostitution have been abolished and venereal disease has been made notifiable

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communication should authenticate them with their names, not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 9661, 9662, 9663, and 9664 (internal exchange four lines)

The **TELEGRAPHIC ADDRESSES** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, Attiology *Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisement etc) *Articulate Westcent, London*

MEDICAL SECRETARY, *Medivecra Westcent London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin*, telephone 62550 Dublin) and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh*; telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Glossitis

"T S S" writes A woman of 40 years has suffered for some fourteen months from a burning and tingling sensation in the tip and sides of the tongue Examination reveals redness, and some swelling of the papillae in these areas Teeth are artificial, and no other abnormality can be found. The patient is a non smoker, and by no means neurasthenic. I would be grateful for advice in treatment

Somnambulism

"C L W" asks for suggestions for the treatment of a boy, aged 7, suffering from sleep-walking For the past twelve months the child has got up and walked in his sleep There is no screaming or emotional disturbance There are no threadworms present and the tonsil and adenoids are normal The treatment given has included glucose at bedtime, hot baths, and luminal bromide seemed to have little effect on the attacks The condition has improved, but the child still walks about once a week

Urinaemia in Prostatic Enlargement

"X" writes In an old case of prostatic enlargement not otherwise needing operation) should signs of uraemia urge immediate operation or the utmost delay The signs are profound sleeplessness (hypnotics nicely for a year past), wasting tremor polyuria and high pressure (200 at intervals urine otherwise normal appetite and strength not much affected dims and blood urea normal blood urea 40 (fasting) and 80 (two and a half hours after urea

Income Tax

Assistant—Board and Lodging

"E. J. S." was engaged as an assistant as from January, 1928, at "£250 per annum and all found." His principal found him board and lodging near the surgery, for which he (the principal) paid £91 yearly. For 1928–29 "E. J. S." was assessed at (£250 + £91 =) £341, but that assessment was reduced on appeal to £250. The inspector of taxes now proposes to reinstate the original £341. Since August, 1930, other furnished accommodation has been found, for which the principal pays £91, and "E. J. S." finds his own board.

*** As regards the period prior to August, 1930, at least, we regard £250 as the correct basis of liability under the old leading case of Tennant *v.* Smith, and we suggest that the inspector should be asked to quote any contrary authority. So far as the year for which the appeal was made and accepted, that decision is final, and no additional assessment for that year can be made. The period subsequent to August, 1930, raises the rather difficult question as to whether or not a new service agreement was not made in effect—in this connexion the change with regard to provision of "board" seems important. If the change was made to suit "E. J. S."—for example, because he had married—and the accommodation was substantially selected by him rather than by the principal, the whole arrangement would probably appear to a tribunal as in substance and effect payment of £341 to be expended as the assistant desired, and they might not altogether unreasonably ignore the mere form of the transaction.

Car Replacement and Depreciation

"Junior" bought a second-hand car (price when new £190) in March, 1928, for £115. In March, 1931, he sold it for £45 and bought a new car for £190, a balance of the purchase price being payable over eighteen months. What can he claim for replacement and for depreciation?

*** Our correspondent is correct in thinking that he cannot claim both as for the same financial year. We advise him to claim replacement cost as a professional expense of the year 1930–31—that is, £115 – £45 = £70—and to allow the depreciation claim for the financial year 1931–32—the year affected by his replacement claim—to go by default. That claim would have been 15 per cent. of £190 = £29, but the claim for that amount will not be permanently lost, provided that when he replaces the second car he claims "obsolescence" allowance.

Expenses of Post-graduate Course

"C. H." took a month's post-graduate course in surgery. Many others were having their expenses defrayed by the Government, but "C. H." was bearing his own expenses. Can he not deduct the expenses for income tax purposes?

*** No; it would be held that such expenses were not incurred in carrying on his professional work, but, during an interval in such work, were incurred to widen or improve his professional knowledge.

LETTERS, NOTES, ETC.

Bilateral Herpes Zoster

Dr. J. S. ANDERSON (Leeds) writes: Dr. Burgess's note on a case of bilateral herpes zoster (August 29th, p. 384) has recalled to me an interesting case of a similar nature which I encountered in 1919, and of which I have still a photograph. A mon [illegible]-woman, aged 30, was in a comatose state when W.3, Wor was called in. She had rather a striking appeas, when her face was covered with a well-developed vesicular tion and The photograph shows numerous vesicles on the for The co cheeks, and chin, with the prominent part of the nose unaffected. There was no rash elsewhere on the body. The woman was sent to hospital with a provisional diagnosis of small-pox—a diagnosis not so surprising if examination was confined to the face. Otitis media was then discovered, and other symptoms pointed to brain abscess. At operation, and later at necropsy, an abscess cavity about the size of a tangerine orange was discovered in the right temporo-sphenoidal lobe.

Pruritus Ani

Dr. F. W. ALEXANDER (Teddington) writes: With great interest I have read in the *Journal* of August 22nd the article on pruritus ani by Colonel Macarthur. Some time ago a medical man consulted me as to whether I could cure him by electricity of intolerable pruritus ani, from which he had suffered for years. His life was a misery, and when playing golf the itching was unbearable. I applied to the outside of the anus high-frequency current by means of an ordinary glass vacuum electrode for a period of about five to ten minutes. Immediate relief was obtained, and a complete cure effected after a few applications. Were the parasites—if present—killed by the electricity? Eberhart considers high-frequency currents capable of traversing long distances in the human tissues.

Maggots in Wounds

Dr. W. W. SHRUBSHALL (Burgess Hill) writes: The article, "Maggots and osteomyelitis," in the *Journal* of September 19th (p. 540), calls to mind an unusual experience which fell to my lot soon after arriving in China in 1888. I was being shown some cases in a ward of a hospital in the Chili Province, and the surgeon—a well-qualified man, though he held no British diploma—took me to the bedside of a patient whose right thigh he had amputated in the lower third, about a week previously. Having but recently come from the theatres of Edinburgh Infirmary, where, during operations, it was then customary for surgeon, assistants, and patient to be saturated with the mists of carbolic sprays, my surprise may be imagined as the dressings were removed from the stump, disclosing a mass of "blow-fly" maggots, whose lively movements caused the bandage to bulge! My friend the surgeon expressed no surprise at this state of the wound; in fact, he said it was not uncommon, and of no importance. Certainly the condition of the patient substantiated the latter part of his statement.

A Visit to S.S. "Orontes"

In aid of the King Edward's Hospital Fund a party was taken down the Thames in steam launches, on September 11th, to be shown over s.s. *Orontes*, the recently built cruising boat of the Orient Steam Navigation Company, which was lying in dock at Tilbury preparatory to sailing for Australia. After leaving Westminster Pier, at 9.30, and making a cold but interesting journey, Tilbury was reached, and parties of ten were conducted over the seven passenger decks of s.s. *Orontes*. The lounges and cafe are decorated luxuriously and in good taste. The same may be said of the special suites, which have green and yellow upholstery and are supplied with flowers, a walnut dressing table, and an electric stove, in addition to the conveniences of the admirable ordinary first-class cabins. These have running hot and cold water, and a bathroom and w.c. connecting. At the end of each corridor is a firescreen door, which, when closed, shuts that corridor off from the rest of the ship. Each cabin can be ventilated by forced draught in tropical temperatures. The services of two doctors are employed, and part of the ship may, if necessary, be converted into an isolation hospital. After being shown over the ship, the members of the party were given an agreeable luncheon on board and taken back to Westminster as they had come.

Correction

In our paragraph on a post-graduate tuberculosis course in Lancashire (September 19th, p. 545), the third sentence should have read: "At the Eccles Tuberculosis Dispensary next morning [October 20th] the value of actinotherapy in tuberculosis will be considered, and also radiology in the diagnosis of the pulmonary form."

Messrs. BURROUGHS WELLCOME AND CO. inform us that Sir Alan Cobham, on his recent air survey of Central Africa, carried with him as his sole medical equipment a small "tabloid" case, which was more than adequate to supply first-aid materials and medicaments for the crew of four persons.

Vacancies

Notifications of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 42, 43, 44, 45, 46, 47, 50, 51 of our advertisement columns, and advertisements of partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page [illegible]

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

248 Etiology and Treatment of Obesity

C. W. NISSLER, EN SHUI TAI, and B. GORDON (*New York State Journ. of Med.*, July 15th, 1931, p. 187), commenting on the lack of constant success in treating obesity by endocrine medication, hold that there is no characteristic disturbance of metabolism in the obese; on the whole their basal metabolism has been found normal, or even slightly above the average. The difference should be sought rather in the manner of their food metabolism. Experiments made in 1928 showed that obese persons on a restricted carbohydrate diet exhibited mild hypoglycaemic symptoms, with sometimes a small drop in blood sugar, easily remedied by sugar administration. A "vicious circle" is suggested, beginning with over-consumption of carbohydrate from greed or example; this is followed by over-production of insulin, and so by a continuation of carbohydrate excess. Observation of 500 obese persons showed that heredity was of less importance than habit and example; there was a general decline in work output and energy, with increase of fat, and increase of hunger and weakness on exertion; tabulation of food intakes showed a normal level of fat and protein intake, but a high level of carbohydrate. Blood-sugar levels were normal in 65 per cent., low in 15 per cent., and high in the remainder; with reduction of carbohydrate, hypoglycaemic symptoms were much more prominent than an actual fall in the blood-sugar levels. Treatment aims at the redistribution of carbohydrate intake, which appears to reduce weight and remove an abnormal desire for food. The plan is to keep patients under observation on their ordinary diet, securing their co-operation in tabulating accurately the daily average intake of food. Later, keeping to the usual meal times, and not altering the protein, fat, or water intake, an attempt is made to reduce the carbohydrate intake by two-thirds. Dextrose, up to a total of 20 to 40 grams daily, is given between meals, at half-hourly intervals in doses of 2 to 4 grams, from 9.30 to 11 a.m., 2.30 to 5 p.m., and 8 to 9 p.m. A satisfactory loss of weight was achieved in 65 per cent. of women treated by this method. The authors insist that increase of carbohydrate intake is the essential factor in the commencement of obesity, and consider that, except in cases of myxoedema and the Froelich syndrome, glandular disturbances in the obese are the effect and not the cause of their condition.

249 Alcohol as a cause of Urethral Discharge

C. M. WHITNEY (*New England Journ. of Med.*, July 2nd, 1931, p. 20) has observed that, during the last ten years in the United States many more cases of non-specific urethral discharge have presented themselves for treatment than previously. Such patients had not been exposed to venereal infection, and bacteriological examinations were negative for gonococci. The type of discharge ranged from the mucoid to the purulent; its quantity varied with the amount of alcohol taken and the varying sensitivity of the urogenital mucous membranes. The most frequent causative agent was found to be synthetic gin. An inquiry addressed to the State Department of Health elicited the reply that repeated experiments had failed to show anything of a toxic nature present in these illicit liquors other than the alcohol itself, the bulk of the fluid being pure ethyl alcohol. Some denatured alcohols, however, contained methyl alcohol. Whitney therefore concluded that the urethral irritation was not due to any chemicals coming over in the distillate, but to the alcohol itself. He suggests that possibly a higher percentage of alcohol is present in synthetic or adulterated liquor. A second factor to be considered is the changed drinking habits of the majority of the people. Since beer is not now obtainable, more whisky and gin are consumed by the people who previously drank it. No case was reported where the drinking had been in moderation. The latent period was usually 24 to 48 hours; there was no dysuria, but a slight prostatic tenderness was detected. The condition usually cleared up quite readily on a mixture of potassium citrate and tincture of hyoscyamus, together with local injections of potassium permanganate or neo-silvol. No complications were observed.

250 Acute Benign Lymphocytic Meningitis

C. BIRET (*Thèse de Paris*, 1931, No. 191), who records nine illustrative cases, one of which is original, in patients aged from 15 to 45, states that acute benign lymphocytic meningitis may be due to a special as yet undetermined virus, an attenuated filterable tuberculous virus, or to the virus of poliomyelitis or epidemic encephalitis. It is characterized clinically by the appearance of the patient, who does not assume the usual hostile attitude, the frequent absence of squint and photophobia, improvement as the result of lumbar puncture, and an invariably favourable course. It is indicated bacteriologically by the absence of tubercle bacilli or any other visible micro-organisms, and cytologically by an abundant lymphocytosis. The increase in albumin is generally moderate compared with the excessive lymphocytosis. The etiology and pathogenesis of acute benign lymphocytic meningitis are still under discussion, but in view of the diplopia and excess of sugar in the spinal fluid in his case Biret is inclined to regard it as a meningeal form of epidemic encephalitis.

251 Multiple Extra-genital Soft Sores

A. CEDERBERG (*Derm. Woch.*, July 4th, 1931, p. 1074), who records an illustrative case, states that an extra-genital soft sore is not a rarity, since Cheinisse collected 99 examples out of 3,536 cases of soft sore. Two kinds of extra-genital soft sore may be described. The first is a heterogeneous form in which the patient contracts an extra-genital soft sore directly from another person, as in a case recently seen by Cederberg of chancroid of the lip resulting from perverse practices; the second and more usual form results from auto-inoculation in a patient with soft sores in the genitals. Cederberg's case was a man, aged 23, who developed multiple soft sores on the prepuce a few days after coitus. About a week later he damaged the middle joint of his left index, which after ten days began to swell. The area surrounding the nail subsequently became affected, and a week afterwards the corresponding area around the nail of the right index was involved. Bacteriological examination of all three lesions showed the presence of Ducrey's bacillus, and also of *T. pallidum*. The Wassermann reaction was also negative. A rapid cure of the adenitis in the axillae was effected by a specific vaccine treatment.

252 Etiology of Coronary Disease

J. B. HERRICK (*Amer. Heart Journ.*, June, 1931, p. 589) believes that the incidence of coronary thrombosis is increasing, possibly owing to the growing frequency of arterio-sclerosis and hypertension, and the greater expectation of life. The role of infection with consequent coronary arteritis is discussed, and it is suggested that some of the patients now suffering from coronary obstruction may date their arterial lesions from the influenza pandemic of 1918. Painless cardiac infarction is mentioned; in these patients a gradual and progressive coronary sclerosis has probably preceded the final occlusion, so that when this occurs the affected region of the heart is already inactive and anaesthetized by ischaemia. Clinical features depend upon the swiftness of the obstruction, and the author suggests that when the failing heart (other than that of rheumatism or syphilis) gives out unusually rapidly, when cardiac asthma and acute pulmonary oedema are

associated with a drop in a previously high blood pressure, and perhaps gallop rhythm and a feeble apex impulse, then probably there has been a coronary occlusion with resulting necrosis. The electrocardiographic abnormalities in infarction are described, and the progressive changes in the curve during the succeeding weeks are stressed. It is believed that further investigations will show the means by which the affected area of muscle and the corresponding vessel may be localized. Reviewing the aortic and coronary hypotheses of the production of pain in angina pectoris, the author mentions among others the following facts in support of the latter theory: the similarity of the pain in angina and that in thrombosis, which is obviously derived from the heart muscle; the rarity of infarction in rheumatic and toxic hearts, in which lesions of the coronaries are very unusual; and the transitory electrocardiographic changes resembling those at the commencement of infarction, which have been observed in some attacks of angina pectoris.

253 Subcutaneous Juxta-articular Nodules

Subcutaneous fibroid nodules of the juxta-articular type were first described by Jeanselme in 1901; syphilis, yaws, and rheumatic and numerous other diseases have been said to be etiological factors. H. H. HOPKINS (*Bull. Johns Hopkins Hosp.*, July, 1931, p. 5) records a study of 14 cases of this condition. In 12 the nodes were syphilitic, and in 2 were associated with chronic infectious arthritis. The former healed completely under anti-syphilitic treatment, the latter did not. The histopathology of the syphilitic nodules was not conclusively characteristic of syphilis, and could not be differentiated from that of the other nodes. Spirochaetes were not found in the syphilitic nodes, and one rabbit inoculation was negative. Hopkins believes that subcutaneous juxta-articular nodules are not pathognomonic of any single disease; they may be simulated by xanthoma.

Surgery

254 The Risk of Embolism from Injected Varicose Veins

O. HORN and J. FOGED (*Ugeskrift for Laeger*, June 11th, 1931, p. 625) note that although the treatment of varicose veins by the injection of chemicals has passed the experimental stage, having proved itself a rational form of treatment for suitably chosen cases, the fear of embolism still deters many from practising it. There are two reasons for this hesitant attitude. In the first place, most of the records of cases of embolism following this treatment are so incomplete that it is difficult to form any definite opinion on the merits of each case, the result being a vague, but general, state of suspicion. In the second place, this treatment is looked at askance by the numerous practitioners who still misunderstand its mechanism, imagining that the injection forthwith promotes a thrombus from the blood present in the vein at the time of the injection. Its action depends, however, on the ability of the injected chemical to injure the intima so that a thrombus is deposited little by little on it, hardening in the process, and finally establishing a firm organic union with the wall of the vein. The ascending venitis (Sicard's "veinite ascendante") may occur as often as once in every hundred injections, however skilfully the injection has been given, and may disturb both the patient and his doctor, but it shows no tendency to provoke embolism. This venitis develops some days after an injection, the vein becoming swollen, tender, and hard, and the skin over it red, oedematous, tense, and shining, for a distance of some 10 to 12 cm.—that is, far beyond the site of the injection. Clinically, this ascending, or chemical, phlebitis differs from the ordinary infectious phlebitis in the absence of severe and persistent pain, in only a slight rise of temperature, and in the disappearance of all the above alarming signs within a few days, whether the patient remains up and about or rests. The authors have neither heard of, nor themselves experienced, a case of ascending venitis ending in embolism, and they trace this immunity to the following facts: the blood stream is usually of low grade in the veins concerned, and the ascending thrombus starts from, and is an organic part of, the thrombus securely established at the site of injection.

255 Treatment of Polyarthritis with Ankylosis

R. LERICHE and A. JUNG (*Lyon Chirurgical*, July–August, 1931, p. 408) describe twenty cases of ankylosis associated with polyarthritis; they conclude that the anatomical morphology of the disease remains constant whatever the causative factor may be. In certain cases the ankylosis is accompanied by an excess of calcium in the blood. In these cases operations on the parathyroids have improved the condition; they should be undertaken as soon as the hypercalcaemia has become established, and before the ankylosis is complete. The progress of the disease is so rapid that this operation is one of urgency. There are three types of polyarthritic ankylosis: cases which have an infectious or gouty origin and in which the calcium content is normal; those in which no infectious cause can be found, but in which hypercalcaemia may be present; and those cases which are accompanied by hypocalcaemia, or normal calcium content, without infection. Of the twenty cases reported, three patients had hypercalcaemia associated with certain clinical signs of hyperparathyroidism. In these cases parathyroidectomy or ligature of the thyroid artery was performed, and was followed by the amelioration of symptoms and the reduction of the calcium contents. In two cases the improvement lasted for four months, and in the third case for six weeks. There were seven cases of unknown etiology in which the calcium was normal or diminished, and ten with definite infectious or gouty origin in which the calcaemia was normal. In these cases operation is of no value.

256 Surgical Treatment of Exophthalmic Goitre

A. LÄWEN (*Zentralbl. f. Chir.*, August 1st, 1931, p. 1938) describes the technique which he finds the most satisfactory in preventing post-operative mortality in Graves's disease. The patient is treated with Lugol's iodine solution for a period ranging from eight days to several weeks, other drugs being used only where there is serious cardiac involvement. During this time the pulse rate and the basal metabolic rate fall, especially during the first few days, as the patient becomes acclimatized to hospital conditions. The weight is considered a better guide to the patient's condition than the metabolic rate; those patients showing a steady loss of weight, in spite of iodine and rest, are always serious surgical risks. The four thyroid arteries are then ligatured in one or two stages. This operation is usually followed by general improvement and increase of weight, though it has little effect on the metabolic rate; occasionally severe and even fatal reactions may ensue. After a period of some weeks thyroidectomy is undertaken. In all operations general ether anaesthesia is used, though in some cases small doses of avertin are given by the rectum. In 100 operations on 48 patients only two deaths have occurred; many had previously received *x*-ray treatment unsuccessfully.

257 Alkaline Incrusted Cystitis

M. ZIGLER (*Urol. and Cut. Rev.*, August, 1931, p. 4[illegible]) who records an illustrative case, states that incrusted cystitis with alkaline urine is caused by the implantation of *B. proteus ammoniae* in a bladder which is already the site of some form of inflammation or tumour. The incrustations are the result of the breaking up of urea into carbon dioxide and ammonia, with the precipitation of *alkaline inorganic salts*. *Trauma* due to catheterization or instrumentation for stricture of the urethra, or to prostatic hypertrophy, or most frequently to childbirth, is the most common predisposing cause. The incrustations may effect either localized areas or the whole of the bladder, but the trigone, internal sphincter, and posterior urethra are areas of predilection. The incrustations may be pointed or flat, or may be associated with calculi. Bleeding surfaces are found when the incrustations are scraped off. Zigler's case was remarkable for the [illegible]

sons. The patient was a man aged 34, whereas most cases occur in older patients; he had injured the right kidney 22 years previously by a fall. *B. proteus ammoniae* was obtained in pure culture from both kidneys by cystoscopy. The case was one of alkaline incrusted cystitis rather than the usual acid incrustation cystitis. The patient was a man, and the number of cases occurring in the female outnumber those in the male by about two to one. There was an associated mild pyelitis, though the great majority of cases have cystitis only. There was no obstruction either in the form of stricture or prostatic hypertrophy. The case was an exception to the rule in alkaline incrusted cystitis in that there was hardly any blood in the urine, whereas in this condition there is usually a large amount of blood and a small amount of pus; this contrasts with ordinary cystitis, in which there is much pus and little or no blood.

258 Syphilitic Synovitis of the Knee

J. S. NEVIASER (*Journ. Bone and Joint Surg.*, July, 1931, p. 566) states that syphilitic synovitis of the knee, especially in children, is very often wrongly diagnosed; a great cause of error is the fact that *x*-ray examinations are always negative. The congenital form occurs as a chronic synovitis, and a persistent hydrops of both knees is not uncommon. Pain and tenderness are less than the swelling and presence of fluid would indicate. In all of the author's cases, the Wassermann reaction of the joint fluid was positive, and also that of the blood in all but one. It is very important to examine both the joint fluid and blood for this reaction, since early diagnosis before bone involvement is most essential; after the bone has been invaded, a resulting good functional joint is doubtful, even though intensive treatment is given. A history of trauma does not eliminate the possibility of syphilis, since association of the two is not infrequent. A relatively painless, chronic hydrops of the knee with a negative *x*-ray examination should arouse a suspicion of syphilis. Early cases respond quickly to specific treatment; in the late second or third stage of the acquired form, treatment is not as beneficial to the joint condition. Abstracts of three illustrative case reports are given.

Therapeutics

259 Treatment of Phlebitis

G. ROSSI (*Il Policlinico*, Sez. Prat., July 13th, 1931, p. 989) records eleven cases of phlebitis in patients aged from 16 to 46, eight of which were post-operative, one puerperal, and two primary, in which Termier's method of application of three or four leeches to the root of the affected limb constantly yielded rapid and brilliant results, as shown by disappearance of the oedema, the rapid disappearance of pain and feeling of heaviness in the limb which is characteristic of phlebitis, the fall of temperature, and the absence of any sequels. The treatment is only suitable for post-operative and puerperal phlebitis, and it is essential for success that the leeches should be applied at the onset of the inflammation.

260 Treatment of Lobar Pneumonia

W. D. SUTLIFF and M. FINLAND (*Journ. Amer. Med. Assoc.*, May 2nd, 1931, p. 1465) comment on the clinical course of Type I lobar pneumonia treated with concentrated pneumococcal antibody (Felton) as observed in 28 patients of a group of 59. In the majority the type of pneumococcus was determined within six hours of obtaining the sputum, and a bivalent antibody, concentrated by Felton's method and potent in mouse protection tests against the pneumococcal Types I and II, was used. The patients treated in this way early in the disease showed a fall in temperature averaging from 20 to 24 hours, as contrasted with a similar fall ranging from 48 to 144 hours in those not so treated; in cases coming under observation after the fourth day from the onset there was no great difference in the average course of the disease between the treated and the untreated patients. The difference in favour of the treated patients was greatest when the injections were given earliest in the disease, and decreased progressively as the treatment was delayed. The specific therapeutic action of the serum was seen in a shortening of the disease, in an immediately striking effect on the bacteriaemia present, in the hindering or preventing of the development of positive blood cultures, and in a diminution in the incidence of spreading areas of consolidation. The authors stress the importance of early diagnosis, rapidity in determining the type of pneumococcus, and the imperative value of specific treatment in lobar pneumonia.

261 Treatment of Pneumonia by Colloid Iodine

Since all cases of pneumonia may be generalized as septicaemic, and markedly beneficial results followed the use of colloidal iodine in a case of pulmonary blastomycosis presenting features of atypical pneumonia, R. V. MURPHY (*Irish Journ. Med. Sci.*, July, 1931, p. 289) has tried this drug in cases of ordinary pneumonias. His results were very encouraging, and he suggests that this treatment may be useful in other conditions also. In the first two cases, 10 c.cm. of a 0.2 per cent. colloidal iodine were injected intravenously; subsequently the strength was increased to 0.4 and 0.8 per cent., and these doses have since been used. There are said to be no contraindications to the use of the drug in pneumonia, and no ill-effects follow its administration; the most striking result is an early abatement of the toxaemia. Primary and recurrent cases respond rapidly and satisfactorily in a few hours, secondary and complicated ones in eight to twelve hours; aged, feeble subjects do not react so well. The earlier that the colloidal iodine is given, the less liability is there to complications and sequels. Though its oral administration is of no effect, the results of intravenous injections can be intensified by introducing the preparation by additional routes. The ordinary routine treatment of pneumonia must be followed, and a favourable environment be maintained. Short, tabulated notes of twenty-seven pneumonic cases treated by this method are appended.

262 Treatment of Secondary Anaemia

K. C. SMITHBURN, J. M. MASTERS, and L. G. ZERFAS (*Journ. Lab. and Clin. Med.*, June, 1931, p. 858) have studied 31 cases of secondary anaemia of various types arising from severe or repeated haemorrhage, infection, cancer, lead poisoning, and one sickle-cell anaemia. As therapeutic agents they employed organic and inorganic iron in solution and in powder; liver; and combinations of liver extract and iron. In the case of sickle-cell anaemia, in two cases of advanced tuberculosis, and in two cases of cancer no response was observed after iron therapy. In some instances there was improvement in the amount of haemoglobin and the red cell count without appreciable reticulosis; in some the colour index was raised; in a few cases the red cells increased in number more than the amount of haemoglobin, and the colour index was lowered. Reticulocytosis began after treatment for four or five days; whereas in pernicious anaemia the reticulocyte response to liver and stomach extracts is not appreciable if the red cells are above 3 million per c.mm., in these secondary anaemias the response was observed when the level of the red cells was above 3 millions. It was concluded that the results of iron therapy are not marked when the amount of iron in the body has been depleted by long-continued anaemia from prolonged loss of blood. The authors consider it reasonable to believe that haemorrhage may cause reticulocytosis, but it does not follow that the patient who has a spontaneous reticulocytosis following haemorrhage, and who continues to bleed, will show an intensified formation of haemoglobin and an increased number of erythrocytes.

263 Cortical Suprarenal Extracts in Addison's Disease

S. L. SIMPSON (*Journ. Physiol.*, June 6th, 1931, p. 4) reports a case of an almost moribund patient with Addison's disease, who was successfully treated with the cortical extract of Swingle and Pfiffner. She received 6 c.cm. of extract intravenously twice a day for four days,

by which time there was obvious clinical improvement. No more extract being available, adrenaline was given hypodermically in 5-minim doses twice a day for two months, since when the patient has maintained good health and gained a stone in weight. The author adds that he has treated five other cases of this disease with the cortical extract made according to the formula of Swingle and Pffifner. The signs of improvement which result are gain in strength and weight, cessation of the nausea and vomiting, and fading of pigmentation ; the symptomatic improvement precedes the rise of blood pressure. Biochemical investigations indicate that the blood urea figure in these cases tends to be high and the blood sugar low. The cortical extract reduces the blood urea content to normal values, but has no immediate effect on the blood sugar ; whether it ultimately causes a rise in blood sugar to normal levels in Addison's disease seems at present to be uncertain. The author suggests that the low sugar figure in this condition may be due to the absence of suprarenal secretion. This is supported by the fact that the figure rises to the normal after hypodermic injections of 10 minims of a 1 in 1,000 solution of adrenaline.

Radiology

264 Radiography of Pulmonary Vessels

E. MONIZ, L. DE CARVALHO, and A. LIMA (*Bull. de l'Acad. de Méd.*, April 14th, 1931, p. 627) have successfully mapped radiographically the network of pulmonary vessels by means of a strong solution of sodium iodide. After several failures when the solution was injected into the subclavian and jugular veins, they heard of Forssmann's success in passing a long sound from the arm into the right auricle. They repeated this manœuvre, and injected 8 c.cm. of an 80 per cent. solution of sodium iodide into the heart, while simultaneously retarding by pressure *the circulation in the thighs, the other arm, and the neck.* Angio-pneumography produces in these circumstances an appearance as if the lungs had been dissected to display the pulmonary vascular tree. Later a stronger solution containing 120 grams of the salt in 100 c.cm. of water was used without ill effect on the patient, save an occasional slight cough. Among possible clinical applications are the diagnosis of vascular and other tumours and the investigation of certain forms of tuberculosis. Further work with this promising new method of investigation is being undertaken.

265 X-Ray Treatment of Agranulocytic Angina

K. NEIDHARDT (*Münch. med. Woch.*, April 24th, 1931, p. 711) reports a typical case of agranulocytic angina, in a female aged 42, who started with the usual severe throat infection. A white cell count of 2,800 per c.mm. was found, 97 per cent. of the cells being lymphocytes. The count sank four days later to 500 per c.mm., and it was decided to try stimulating doses of *x* rays to the bone marrow, according to Friedemann's suggestion ; 5 per cent. of an erythema dose was given over the femora and tibiae through a hard filter. The white cell count rose within a few hours, and reached 3,800 two days later. The treatment was repeated over the arms, and a leucocytosis gradually produced, the polymorphs (and a few myelocytes) returning to the circulation. Although the prognosis in this condition is bad, 90 per cent. of cases being fatal, this patient made a good recovery.

266 Intravenous Urography

K. HERITAGE (*Practitioner*, March, 1931, p. 343) strongly recommends abrodil for intravenous pyelography. This drug is sodium mon-iodo-methane-sulphonate ; it contains 52 per cent. of iodine in contrast with the 42 per cent. content of uroselectan, and is soluble in water up to 70 per cent. Its administration is free from immediate symptoms, such as generalized tingling and feeling of heat, and very often there is no sensory disturbance of any kind following its intravenous administration. When there was slight leakage of the solution from the vein after puncture, or a small perivenous injection had been accidentally made, no ill effects beyond a transient local pain were noticed, and the vein was not thrombosed. The patient is prepared in the usual way for renal radiography, the colon being emptied as far as possible, and the intake of fluids being restricted for some time before the injection. The first film was taken five minutes after the injection ; others were taken at the end of about fifteen and twenty-five minutes, or later if the renal function was deficient. As soon as the last film has been taken the patient is given fluids in order that the elimination of the drug may be hastened. Heritage adds that the only contraindications to this method are acute infections of the urinary tract and latent or manifest uraemia.

267 Radiography of the Chest

H. A. JARRE (*Zentralbl. f. Chir.*, February 28th, 1931, p. 526), using serial photographs (four per second), with or without the previous injection of lipiodol, has studied the movements of the thoracic viscera in health and disease. He states that in children the mediastinum is very mobile, and subject to considerable variations in shape, being influenced by cardiac and respiratory movements, etc. A wide convex upper mediastinal shadow should not be taken as definite evidence of an enlarged thymus, unless it is constantly present and there is also evidence of pressure on other structures such as the trachea. True peristaltic movements in a central direction can be demonstrated in the normal bronchi, especially during expiration. The alveoli do not take part in these movements. The sphincter-like muscles of the atria keep lipiodol out of the alveoli, unless there has been coughing, or emphysema is present. In the latter condition lipiodol readily reaches the alveoli, and by reducing the aerating surface may give rise to unpleasant effects. Infection of the bronchial walls, as in bronchiectasis, interferes with peristalsis, so that a vicious circle is established, the infected bronchus being unable to empty itself of secretion. In bronchial asthma there is spastic narrowing of the bronchial lumen with hyperperistalsis. Alteration of the peristaltic phase has been noted in some cases, the contractions occurring during inspiration.

Obstetrics and Gynaecology

268 Primary Carcinoma of Fallopian Tube

J. RABINOVITCH and J. D. HORTON (*Amer. Journ. Obstet. and Gynecol.*, May, 1931, p. 689), who report an illustrative case, remark that primary growths of the Fallopian tube are not very frequent, and, owing to their great similarity to other pelvic conditions, are seldom recognized before operation and pathological examination of the specimen. The disease usually occurs in persons at or past the menopause, when all other types of malignant tumours are most frequent. The true nature of the primary growth is apt to be overlooked owing to the frequency of secondary inflammatory changes. The commonest symptoms are watery or sero-sanguineous vaginal discharge, with or without abdominal pain. Both the pain and the discharge may vary in character and severity in different individuals, and in the same individual at different times. According to the size and position of the tumour in the pelvis, there may be urinary or intestinal disturbances such as frequent or urgent micturition and constipation. Marked loss of weight and cachexia are seldom observed, but under-nourishment and anaemia are not infrequent. The size of the tumour ranges from that of the little finger to that of a large mass filling the abdomen. The growth is fixed or freely movable according as inflammatory changes with productive adhesions have occurred or not. The middle or distal third of the tube is the commonest site for the tumour, which may be unilateral or bilateral. The most frequent histological varieties are the papillary and the papillary-alveolar, various modifications of these two patterns being encountered in different tumours. The case recorded by the present authors occurred in a woman, aged 55,

had had three full term pregnancies and had reached the menopause five years previously For the last two years she had had a watery vaginal discharge, which had been more profuse and continuous during the five months before admission to hospital, and had become sanguineous during the last three weeks The uterus was small and retroverted, the adnexa were not palpable A diagnosis of malignant discharge of the uterus was made, and laparotomy was performed The uterus, ovaries, and right Fallopian tube appeared normal, but the left Fallopian tube was enlarged in its distal third Although the gross appearance of the tube was indistinguishable from a chronic inflammatory process, the confinement of the lesion to one part of the tube suggested malignancy, and panhysterectomy was performed No histological abnormalities were found in the uterus, ovaries or right Fallopian tube, but section of the left tube showed the appearance of a papillary carcinoma

269 Pregnancy complicated by Systemic Disease

Believing that the pregnant woman can be better studied, diagnosed, and treated if emphasis is placed on any complicating medical condition, P A DALY and S STROUSE (*Journ Amer Med Assoc* May 16th, 1931, p 1655) support this view by discussing pregnancy complicated by diabetes, cardiac disease, and thyroid disturbances, and cite illustrative cases They conclude that, though pregnant diabetics present dangerous difficulties, with care and strict attention to diabetic therapy such patients can be carried through to normal delivery They find no appreciable difference between cardiac patients who have gone through a pregnancy and those with similar heart lesions who have not done so, repeated pregnancies may, however, be inadvisable Treatment should maintain or increase the cardiac reserve in order to provide sufficient muscular efficiency for the maximal work of labour and delivery, this is best attained by a proper balancing of rest and work A diseased heart which has not failed during pregnancy and is not decompensated, should not fail during delivery Hearts decompensated at the time of delivery present a grave prognosis, and the result is usually fatal Spontaneous labour with forceps aiding delivery is the method of choice in most cases, but is inadvisable when early delivery is desired or subsequent pregnancies are deemed unwise, Caesarean section is best in these Pregnancy has an influence on the thyroid gland, and even those thyroids usually called normal are subject to changes during pregnancy Disturbance of the thyroid function may be a factor in producing some of the toxaemias of pregnancy, six cases are cited in support of this view In these patients, the metabolic rate which increases in normal pregnancies, should be increased by appropriate thyroid treatment

270 Ambulant Treatment of Chronic Cervicitis

SUSAN R OFFUTT (*Minnesota Med*, June, 1931, p 507) outlines a method of treating chronic cervicitis without enforcing confinement to bed The chief objectives of such treatment are the relief of annoying leucorrhoea, the removal of a chronic inflammatory lesion which may be pre cancerous, and the elimination of a possible focus of infection Chronic cervicitis is the chief form of leucorrhoea, and is frequently characterized by erosion For mild cases treatment by means of cauterization, with or without anaesthesia, can be undertaken in the surgery The infected glands must be completely destroyed by a number of incisions Few patients complain of pain beyond that comparable to a menstrual cramp In most cases the necessary cauterization can be completed at one session The sloughing is allowed to proceed without interference, and the patient is examined every three to four days The discharge increases at first, but usually stops in ten to fourteen days Complete healing does not occur for about two months After the sloughing period is over douches are used, and the cervix may be treated locally twice a week with mercurochrome until it has healed Possible complications in cauterization of the cervix are haemorrhage, stenosis, and pelvic infection If the cauterization is undertaken near a menstrual period there may be profuse menstrual bleeding afterwards when this occurs the patient is put to bed and given ergot Stenosis is a rare complication, necessitating dilatation of the canal under anaesthesia Pelvic infection does not ensue if precautions are taken not to cauterize a cervix which is the seat of an acute infection, particularly that due to gonorrhoea with or without salpingitis Cauterization of the cervix has proved to be good treatment in mild and moderately severe cases, in extensive disease an operation becomes essential

271 Somnifen in Eclampsia

J LARRIBERE (*Bull Soc d Obstet et de Gynecol de Paris* June, 1931, p 461) discusses the treatment of eclampsia by somnifen, and reports fifteen cases which were completely successful, as regards both mother and infant the crises were controlled instantly and definitely When the fits cease, elimination of the toxins and an appropriate regime can be adopted with the view of preventing recurrence The author employs a dosage of 3 to 5 c cm according to the obesity of the patient An intravenous injection of 3 c cm produces sleep in less than one minute He has found that evacuation of the uterus is not necessary if somnifen is given during the first fit He describes the case of a 2 para aged 21, and with no previous history of eclamptic attacks When seen by Larribere she had had four convulsions during the previous hour She was comatose and stertorous and the lower limbs were oedematous One typical eclamptic convulsion was witnessed, and a sixth began while the injection was being prepared An intravenous injection of 4 c cm of somnifen was given The patient fell asleep in 30 seconds and had no further convulsions

272 Carcinoma of Uterus and Fallopian Tubes

J A FERGUSON (*New England Journ of Med* June 25th 1931, p 1359) records a case of epidermoid carcinoma of the uterus and Fallopian tubes in which there was an unusual sequel to radium treatment The patient aged 40, complained of a vaginal discharge, lower abdominal pain and weakness which had persisted for two years, cervical carcinoma and an adeno-acanthoma in the fundus were found as the result of curetting Improvement followed four heavy radium treatments, the discharge ceasing, but returning two years later when panhysterectomy was performed No extension of the disease or metastases were found, and recovery was uneventful The cervix was fibrosed and showed no trace of the original epidermoid carcinoma the adeno-acanthoma had disappeared, and was replaced by a surface growth of malignant squamous-cell epithelium, without any invasion of the myometrium or pearl formation The uterine cavity was filled with yellowish keratinous debris, and there was no sign of continuity of growth between the fundus and the Fallopian tubes While the condition of the tubes was probably secondary to the disease of the fundus, it was impossible to rule out a primary malignant squamous-cell metaplasia of the tubal epithelium, or a tumour embolus having been forced into the isthmus through the intrauterine part of the tube A similar appearance occurring in the uterus and tubes of guinea pigs fed on a vitamin A deficient diet has been described as having both a gross and to some extent histological, resemblance to that found in this case

273 Treatment of Hyperemesis Gravidarum

J E HOUEL (*Bull Soc d Obstet et de Gynecol de Paris* April, 1931, p 235) regards isolation of the patient or her removal from the usual surroundings, as an indispensable measure in treatment of severe cases of hyperemesis gravidarum He records two such cases in one of which the induction of abortion had almost been decided on the acidosis quickly disappeared, and the vomiting subsequently ceased, after the injection twice daily of 10 units of insulin, and a daily subcutaneous injection of half a litre of glucose saline solution It is advisable before using insulin in these patients to estimate the blood sugar even if the figures are normal, sugar should be administered —orally if retained, in mild cases—at the same time

Pathology

274 The Vitamin Content of Fermented Milks

K. A. FORSTER (*Biochem. Zeit.*, July 6th, 1931, p. 276) has compared the vitamin content of raw milk with that of yoghurt, kefir, and saya. The estimation of vitamin A and D was carried out on rats, of C on guinea-pigs, and of B on pigeons and rats. The results were as follows. Yoghurt is richer in the fat-soluble vitamins A and D, presumably because during its preparation it undergoes a certain amount of evaporation, and is higher, therefore, in its fat content; on the other hand it is poorer in the water-soluble vitamins B and C. Kefir is poorer than raw milk in vitamins A, C, and D, and has about the same content of B. Saya has much the same content as raw milk of vitamins B and D, but its A content is about double that of raw milk, and its C content is about one-third higher. Whereas, therefore, the vitamin content of yoghurt and kefir is on the whole less than that of raw milk, saya apparently maintains its original vitamins intact, and has an increased content of A and C. The vitamin loss with yoghurt and kefir is understandable, since both these products are heated during preparation under aerobic conditions. Saya is prepared by allowing the milk to ferment at a lower temperature for a period of six weeks under anaerobic conditions; the predominant flora apparently consists of lactic acid streptococci, *Strep. citrovorus, Strep. paracitrovorus,* and *Bact. acidi lactici*; the milk becomes highly acid, and there is a very marked breakdown of the casein. The increased content in vitamins A and C which occurs in saya is believed to be the result of bacterial activity during preparation.

275 The Transmission of Trachoma and Cultivation Experiments

P. K. OLITSKY, R. E. KNUTTI, and J. R. TYLER (*Journ. Exper. Med.*, July, 1931, p. 31) have succeeded in transmitting trachoma to *Macacus rhesus* monkeys; some of the methods resembled those probably responsible for the spread of the disease under natural conditions. Infected conjunctival tissue from white patients of various nationalities in New York was ground up in saline solution and inoculated subconjunctivally into the left upper lid of monkeys. The material from 5 out of 8 patients gave rise in these animals to the characteristic infection. Examination of the original material revealed the presence of *Bact. granulosis* in 4 out of the 8 patients, and in 3 out of 4 of the inoculated monkeys in which it was looked for. Successful infection was likewise transmitted by repeated swabbing with the conjunctival secretion of trachomatous patients. Similarly the disease could be transmitted by the swabbing of normal monkeys with conjunctival secretion from experimentally infected animals. Repeated instillation of pure cultures of *Bact. granulosis* into the conjunctival sac proved harmless, but if, after inoculation, the eyelids were rubbed gently for about a minute, granular conjunctivitis ensued. Contact infection was sometimes observed, healthy monkeys developing trachoma when caged with infected monkeys. The authors conclude that these results strengthen the view, first advanced by Noguchi, that *Bacterium granulosis* is closely related to human trachoma.

276 Cyclic Changes in the Glycogen Content of the Liver

G. ÄGREN, O. WILANDER, and E. JORPES (*Biochem. Journ.*, 1931, vol. xxv, No. 3, p. 777) submit evidence that the glycogen content of the liver in rodents is subject to a marked diurnal variation, being considerably higher during the night than the day. This variation was noticed by Forsgren, who, working on histochemical methods, likewise found that there and is some corresponding periodicity in the production of l[illegible]ncentration is free from [illegible]put of this substance occurring d[illegible]ized tingling and [illegible]e glycogen content of the liver w[illegible]s no sensory disturbhors have worked with mice an[illegible]enous administrations, and with rabbits for mea[illegible] the solution from[illegible]n. The general plan of the experiments was to select a batch of 90 or 120 animals, and kill 10 animals every two hours during the day and night, or 15 animals every four hours, commencing at 8 a.m. The glycogen content of the liver was estimated, and the results worked out in milligrams per gram of body weight. Sometimes the animals were well fed; in other experiments they were examined fasting. In some experiments the susceptibility to insulin was determined. The results were very striking. In well-fed mice the average glycogen content of the liver at noon was 0.62 mg. per gram of mouse, while at midnight it was 2.06 mg. The minimum content of 0.56 mg. was observed at 10 a.m., and the maximum of 2.51 mg. at 2 a.m. A similar diurnal variation was observed in fasting animals. The susceptibility to insulin was higher during the day than the night. Thus the percentage of mice developing convulsions after a given dose at noon was 60, whereas at midnight only about 12 per cent. became convulsed. Studies of the urinary nitrogen output in rabbits showed that about 20 per cent. more nitrogen was excreted by the urine during the night than during the day. The authors take this as indicating an increased de-amination of amino-acids during the night, and therefore conclude that the formation of glycogen takes place partly at the expense of the body proteins. The glycogen content of the muscles was found to show a slight nocturnal rise; this is taken to indicate that the muscular glycogen during the night originates from the liver.

277 The Blood Picture in Whooping-cough

L. W. SAUER and L. HAMBRECHT (*Amer. Journ. Dis. Child.*, June, 1931, p. 1326) record their observations on leucocyte counts and differential counts in 70 cases of whooping-cough in patients whose average age was between 4 and 5 years. Since the greatest variations were found in the catarrhal stage and the stage of decline, most of the repeated examinations of the blood were made at the beginning and at the end of the disease. The characteristic leucocytosis and lymphocytosis were always found when the paroxysmal stage was at its height, whereas an initial and a terminal leucopenia were found in almost every instance in which they were sought. During the terminal leucopenia there was a decrease in the number of lymphocytes. Similar results were obtained in experimental pertussis in young monkeys. Five of the seven animals that developed paroxysmal coughs showed an initial leucopenia, and three of the four that were not killed for histological examination showed terminal leucopenia. The authors conclude that while early and late leucopenia are integral parts of the blood picture in pertussis, the blood picture is seldom an aid in early diagnosis of the disease.

278 The Leucocyte Reaction in Syphilis

J. GOUIN, A. BIENVENUE, DAOULAS, and PÉRÈS (*Bull. Soc. Franç. de Derm. et de Syph.*, June, 1931, p. 860) describe the case of a woman, aged 42, with papular syphilides; a preliminary injection of novarsenobenzol was followed two hours later by a leucopenia. Although such a leucopenia has been regarded by some observers as contraindicating a diagnosis of syphilis, arsenical treatment was continued; the patient developed intolerance, and did not improve. Bismuth therapy also was followed by leucopenia, and was not tolerated. Mercurial treatment was finally tried; this was followed by leucocytosis, general clinical improvement, and eventual retrogression of the lesions. They conclude that "leucocyto-reaction" is of diagnostic value only when positive—that is, when the injection of an anti-syphilitic remedy is followed after two hours by a leucocytosis. Unless it is negative with every therapeutic substance, a negative reaction does not *disprove* syphilis, but only indicates a resistant state, as opposed to the allergic state, produced by the drug used. An interesting point with regard to the case described, was that a relapse in the lesions occurred after mercurial treatment, and that a return to bismuth was followed by a positive leucocyte reaction, and improvement. Hence, a negative reaction may be held to indicate a resistant state towards a particular drug present only at one period.

WHETHER THE PATIENT IS

aged  and feeble  or so young  that his digestive system works less energetically than his limbs  or is an adult business man  healthy but deskbound  — prescribe AGAROL with confidence for the relief of constipation and to aid in restoring regular bowel function.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Gentle enough for little patients; active enough for the chronic state of the adult and aged patient.

A supply gladly sent for trial.

AGAROL BRAND COMPOUND *for Constipation*

FRANCIS NEWBERY & SONS, LTD., 31-33, Banner Street, London, E.C.1.

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists since 1856.*

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me";* without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

An IMPROVED and MODIFIED
Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in polished case 35in. × 11in. × 11in.

AN INTERESTING LEAFLET [illegible] diagrams and instructions [illegible] on request. Please ask [illegible]

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

CITY OF LONDON MENTAL HOSPITAL, DARTFORD, KENT.

Ladies and Gentlemen suffering from mental affections under certain conditions of age can be received as either VOLUNTARY or TEMPORARY PATIENTS at a weekly fee of TWO GUINEAS and upwards.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. *The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free* of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

The salary will be at the rate of £400 per annum, rising by annual increments of £25 to £450 per annum, with emoluments valued at £150 per annum.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him

The appointment will be subject to the Birmingham Corporation's Superannuation Scheme, and to the candidate passing a medical examination, and will be subject to one month's notice on either side

Forms of application may be obtained from, and should be returned, with three testimonials to, the Chief Clinical Tuberculosis Officer, 44a, Broad Street Birmingham, by 9 o'clock on October 3rd

F. H. C. WILTSHIRE,
Town Clerk.

Council House,
Birmingham.

County Council of Middlesex.

THE COUNTY (TUBERCULOSIS) SANATORIUM, CLARE HALL, SOUTH MIMMS, MIDDLESEX.

ASSISTANT RESIDENT MEDICAL OFFICER.

The County Council invite applications for the post of Assistant Resident Medical Officer (male) at the above Institution, at a salary of £400 per annum, rising by annual increments of £50 to £600 per annum, with board, lodging, and laundry, valued at £100 per annum

Candidates must be registered Medical Practitioners, not over thirty-five years of age, unmarried, and of British nationality They must have held resident Hospital appointments Practical experience in the diagnosis and treatment of Tuberculosis will be an additional qualification

The officer appointed will be required to devote his whole time to the duties of the post, and to contribute to the County Council's Superannuation Fund. For the latter purpose he will be required to pass such medical examination as the County Council may direct

The appointment will be during the pleasure of the Council, and subject to one month's notice on either side.

Applications, stating (1) name, (2) age, (3) experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than October 2nd No special application forms are provided Envelopes must be endorsed "Assistant Medical Officer, Clare Hall"

Canvassing, directly or indirectly, will be a disqualification.

ERNEST S W. HART,
Clerk of the County Council.

APPOINTMENTS.—Contd.

Belgrave Hospital for Children (Incorporated), 1, Clapham Rd., S.W.9.

The Committee of Management invite applications for the posts of TWO HOUSE PHYSICIANS, which will become vacant on *October* 31st next.

Applicants, men, must be fully qualified and registered. The appointments are for six months, with board, residence, and washing provided. Salary at the rate of £100 per annum.

Applications, with copies of testimonials, stating age, should be forwarded on or before Thursday, October 8th, to the Secretary.

City of Portsmouth,

THIRD ASSISTANT RESIDENT MEDICAL OFFICER.

The Corporation invite applications for the appointment of a Third Assistant Resident Medical Officer for the Saint Mary's Hospital, St. Mary's Institution, and Children's Home.

The appointment will be limited to a term not exceeding one year, and will be subject to one month's notice on either side.

Salary at the rate of £250 per annum, with furnished apartments, rations, and other allowances.

Candidates must be single gentlemen, and duly registered. Preference will be given to those having a knowledge of the treatment of Mental Diseases, and who have experience in Surgical work.

A Resident Medical Superintendent is in attendance.

Applications must be made on printed forms (which may be obtained at 1, St. Michael's Rd., Portsmouth), accompanied by copies of not more than three recent testimonials, and a description of the diplomas, certificates of degrees, licences, and other instruments held by the candidates, must be returned to the Acting Public Assistance Officer, 1, St. Michael's Rd., endorsed "Third Assistant Resident Medical Officer," by Tuesday, October 6th.

The Guildhall, F. J. SPARKS,
Portsmouth. Town Clerk.
September 14th, 1931.

The Queen's Hospital for CHILDREN, Hackney Road, London, E.2

The Committee invite applications for the post of SURGEON for the Ear, Nose, and Throat Department, with charge of beds. Attendance required on Monday and Thursday mornings. An honorarium to cover travelling expenses will be paid. Candidates must be Fellows by examination of the Royal College of Surgeons, England.

Applications, with copies of three recent testimonials, which may be printed or typewritten, should be sent on or before October 27th, to the undersigned, from whom further particulars may be obtained.

CHARLES H. BESSELL,
September 17th, 1931. *Secretary.*

Caernarvonshire and Anglesey INFIRMARY, BANGOR.

GENERAL HOSPITAL.

Wanted, RESIDENT HOUSE SURGEON (male) and JUNIOR RESIDENT HOUSE SURGEON. Must be fully qualified. Salary £150 and £100 respectively, plus board and laundry. Hospital contains Orthopædic, Ear, Nose, and Throat, X-ray, Radium, and Light Departments. The appointments offer good opportunities for practical surgical work. Applications, addressed to the Secretary, to be sent in by September 29th.

Kent and Canterbury Hospital, CANTERBURY.

(Recognised by the University of London for the purpose of M.S. EXAMINATION)

HOUSE SURGEON required. Six months' appointment. Salary payable at the rate of £125 per annum, plus board, residence, and laundry.

THE MOST EFFECTIVE TREATMENT IN PNEUMONIA — INFLUENZA CORYZA

is provided by

EDWENIL

The Original Polyvalent Antibody.

A typical pneumonia report states:

"Male adult, admitted to hospital on the second day of illness, suffering from double lobar pneumonia. His condition appeared hopeless. He was very deeply cyanosed, pulse 140, respiration 48, temperature 103·2°.

"2 c.c. of Edwenil were given, followed by a fall in temperature to 99° in 12 hours. A second dose of 2 c.c. was given. Temperature rose to 102·4 and fell again in another 12 hours.

"This cycle was repeated and temperature reached normal on the 6th day. Six hours after the first injection, it was obvious that he was more comfortable. The cyanosis began to subside on the second day. From that time improvement was rapid and uneventful."

A sufficient quantity of EDWENIL, to demonstrate its activity in your own practice, will be sent without charge. Write or telegraph

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the band to the immovable zero.

Care should be taken to avoid close imitations. Look for the trade mark "TYCOS" engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

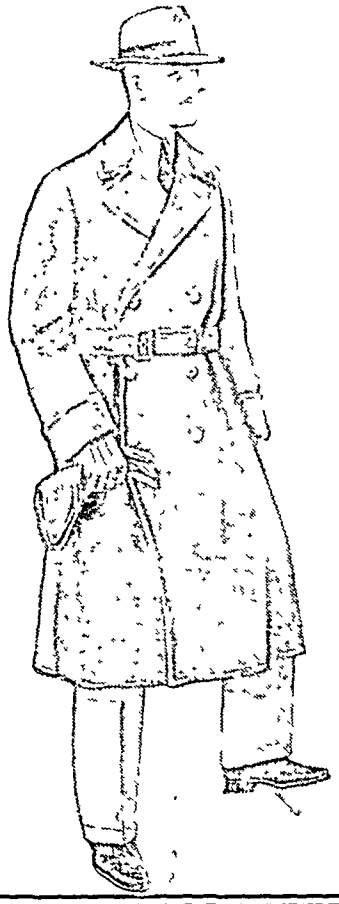
WHERE APERIENTS FAIL SURGICAL BELTS SUCCEED!



The introduction of X-ray photography has swept away many previously held conceptions of the pathology of the abdomen. This new method of examination has shown unmistakably that therapeutic measures such as the use of aperients and intestinal antiseptics are futile in the presence of mechanical displacements. It has revealed that the safe, scientific and effective measure in innumerable cases is to correct the mechanical fault in the engineering system of the abdomen by suitable upward support. Such support is given in specific complaints by Domen Surgical Belts.

Domen Surgical Belts provide ample support upwards from the pelvis. They counteract the downward pull of gravitation—the underlying cause of mankind's tendency to sag. And Domen Belts achieve this upward support without cramping or binding the patient. Domen Belts are light, and durable, and strong. On receipt of your card or a telephone request, full particulars will be forwarded.

DOMEN SURGICAL BELTS

PAR EXCELLENCE

THE DOCTOR WHO TELLS HIS PATIENT..

to obtain a Spencer Support, can do so with the knowledge that the Spencer Corsetière will give his patient SERVICE in the fullest meaning of the word.

He can feel that there will be no annoying complaints that the garment bulges here and there; that it is too much like a "harness"; that it isn't comfortable; that it doesn't wear well.

Spencer *individual designing* service assures you and your patient that the support will be

. . . Designed from the patient's measurements for the *specific purpose* for which you recommend it.

. . . Expertly tailored of *tested* materials, that out-wear all others, and will

. . . Provide perfect comfort and will *give good style lines.* Thus one garment suffices for both style and surgical needs!

AND, MOST IMPORTANT, IT WILL BE FAITHFULLY SERVICED BY THE CORSETIÈRE, WHO WILL KEEP IN TOUCH WITH THE PATIENT TO ENSURE *PERMANENT* SATISFACTION.

When a Doctor prescribes a Spencer support, he can safely throw off all further responsibility for the fit and satisfaction of that garment, and be assured that it is fulfilling the mission for which it was prescribed.

Years of acceptance of Spencer supports by the medical profession of the world enable us to make these statements.

AUTHORITIES ENDORSE ALUMINIUM FOR HYGIENIC COOKING

Aluminium ware has grown in popular favour by reason of its hygienic, economic, and labour-saving qualities. As to its safety in the kitchen, it carries the full endorsement of investigating authorities in Great Britain and the United States of America, and on the Continent.

3 GERMAN

THE GERMAN OFFICIAL BOARD OF HEALTH (Aus Reichs-Gesundheit Blatt, No. 41, 8/10/'30) "The Board of Health has made further researches on this point, which is important for public health. In these tests, the effect of feeding Aluminium compounds, particularly Aluminium hydroxide, was found in water boiled in Aluminium utensils in varying small quantities according to the nature of the water and the length of time boiled, was tried on animals—dogs. The tests were carried out over a period of many months. The condition, appetite, and body weight of the animals under test underwent no injury, neither macro- nor microscopic changes could be found in the organs of the animals. The behaviour of large quantities of Al (1,000 mg. Al_2O_3) in the stomach of human beings was also investigated. No Aluminium except traces that are normally present could be found in the urine. No injury to the system whatever, or even any deprivation of normal health was observable. These results confirm the results of previous investigations by the Board of Health."

A résumé of published evidence by British, American and Continental medical authorities, will be sent gratis on request.

ALUMINIUM INTELLIGENCE BUREAU. Adelaide House. London. E.C.4.

BMJ 2 10 31

X-RAY YOUR PATIENTS

wherever they are at surprisingly low cost—

Negatives developed within 10 minutes—perfect results assured

X-ray examinations can now be made at the patient's bedside—anywhere—at any time. Powerful portable apparatus is available day and night for service—under the control of expert radiographers—and within forty minutes of the arrival of the Service Car at the door of your patient's house, negatives are ready for inspection. The films are developed on the car, which is fitted up as a dark room—and the taking of the radiographs can be conducted throughout under the supervision of the medical practitioner concerned. Great penetration of any part of the body is ensured, and the definition of the negative is rendered equal to that of any permanently installed apparatus.

During the last seven years over 1,000 doctors have availed themselves of X-RAY CAR SERVICE.

Full details in the form of an interesting descriptive booklet, will gladly be sent on request.

Write, wire, or telephone to-day

The charges are graded according to the distance travelled from London—the basic charge within a 10 miles radius being only four guineas, and one guinea for each subsequent radiograph at the same visit. Special terms for hospitals.

Vaccine therapy for Common Colds

The logical treatment for common colds, by supporting the anti-bacterial functions of the mucous membrane and stimulating the immunity mechanism, is the use of a bacterial vaccine containing the groups of bacteria commonly associated with such respiratory infections.

Catarrh "Cold" Serobacterin Mixed, Mulford, a sensitized bacterial vaccine containing such micro-organisms, has been successsfully employed in both the prophylaxis and treatment of the various infections of the upper respiratory tract.

HORLICK'S *for*
The EXPECTANT MOTHER

When added to the diet of expectant mothers *Horlick's Malted Milk*:—

1. *Provides extra nourishment* in an easily digested and assimilated form. Horlick's causes no digestive disturbances.

2. *Helps the elimination of waste products.* Constipation is frequently a troublesome feature of pregnancy. Horlick's promotes good bowel habits, and prevents constipation. As a food-drink it helps elimination by the kidneys.

3. *Prevents and relieves morning sickness.* The easily assimilated carbohydrate content of Horlick's Malted Milk counteracts the mild toxaemia, which causes many cases of morning sickness.

4. *Promotes sleep*—sleeplessness frequently complicates pregnancy, and adversely affects its course by increasing both worry and fatigue. Horlick's, by promoting sound sleep, places the patient in a favourable position to counteract these adverse influences.

Horlick's Malted Milk Co., Ltd., Slough, Bucks.

WHEN EXHAUSTION PROHIBITS SOLID FOOD . . .

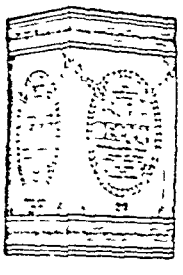
WHEN ANOREXIA RETARDS RECOVERY . . .

In serious illness when vitality is at its lowest and solid foods are prohibitive, these essences are of inestimable value.

Combining quick stimulation with almost effortless assimilation Brand's Essences of Beef or Chicken revive vitality while conserving the patient's energy.

99 out of every 100 doctors recently interviewed recommend them in illness and convalescence.

Even in cases of advanced stomach atonicity, Brand's Essences mean a quick return to normal tone and acidity.



Suave and non-irritating, prepared by an exclusive process from the finest freshly killed English meats. No preservatives or colouring matter are used. They are easy to swallow and deliciously appetizing.

Samples will be gladly sent on receipt of a professional card. Dept. F40, Brand & Co., Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

BY APPOINTMENT

BRAND'S ESSENCES OF BEEF OR CHICKEN

Has the Ordinary Diet Sufficient Vitamin B?

Laboratory Reports on Bemax and Clinical Sample for personal trial will be sent to any Medical Man on request.

At the request of many correspondents a series of tests were recently conducted at the Bemax laboratories to determine how far the ordinary daily diet is an adequate source of Vitamin B.

The diet chosen for the tests included Eggs, Bacon, Bread, Butter, Beefsteak, Cabbage, Potatoes, Cheese, and a suitable percentage of A and D Vitamin.

The results prove conclusively that such a diet is in fact deficient in B Vitamin and cannot, by itself, meet the nutritional requirements of adults or promote normal growth in children.

Ample evidence is already available to show that partial B Vitamin deficiency results in a progressive deterioration of the digestive system, and may well be the principal cause of the many intestinal complaints which are so common to-day.

Bemax provides an ideal way of supplementing the ordinary diet with an adequate supply of B Vitamin, of which it is the richest known source in B, Bii, and Biii.

Its value as a tonic restorative food can hardly be over-estimated and its use has been attended with striking results in Dyspepsia, Constipation, Sleeplessness, Nervous Debility, Rheumatism, and all B deficiency diseases. As its content of E Vitamin is also exceptionally high it can be used with great advantage in the treatment of Sterility.

Medical Men are invited to write for reports of the tests referred to in this advertisement.

BEMAX

THE NATURAL VITAMIN TONIC FOOD

THE BEMAX LABORATORIES, 23, Upper Mall, Hammersmith, London, W.6.

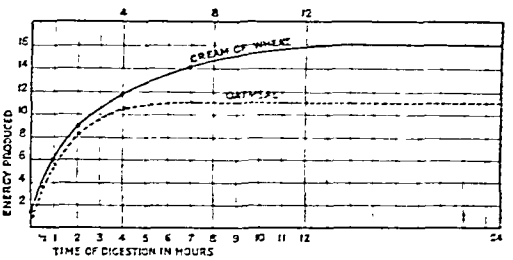
After Milk—WHAT?

"Infants even as early as the third month will digest appreciable quantities of starch."*

The statement reflects the growing tendency among medical practitioners to-day, to introduce a starchy food into infant diet at a much earlier stage, than was hitherto considered necessary or advisable.

Four noteworthy advantages of early starch feeding given recently by a leading pediatrist are:

Slower carbohydrate digestion, allowing thorough hydrolysis lasting over a period from one feed to another.
Less tendency to fermentative diarrhœa.
Metabolisation of fat.
Retarded curd formation.



Research Institute proves "Cream of Wheat" to be more digestible than oatmeal and productive of 50% more energy

"Cream of Wheat," long successful as a food for infants, has now been proved by a leading British biochemical institute to possess definite advantages over oatmeal.

Reference to recent text-books and monographs shows that many of the leading pediatrists of the day have placed this wheat-cereal on their diet sheets for infants.

It is made from the best hard wheat and has a starch content of 72 per cent. Containing none of the husk, it causes no irritation in the intestinal tract, and can be confidently given not only to infants, but to adults during the post-operation period and convalescence.

A sample of "Cream of Wheat" and a full account of the tests described here will gladly be sent on receipt of your professional card. Dept. W9, Fassett & Johnson, Limited, 86, Clerkenwell Road, London, E.C.1.

Replica of graph showing Diastatic Digestion of "Cream of Wheat" compared with that of oatmeal. After 4 hours the digestion of oatmeal was practically at a standstill, while that of "Cream of Wheat" continued at a scarcely diminished rate for a further 4 hours. Further, the sugar yield from "Cream of Wheat" was 50 per cent greater than oatmeal—making it productive of 1½ times as much energy.

*"Infant Feeding," by Clifford G. Grulee, A.M., M.D., LL.D. (J. & A. Churchill).

The French Natural Mineral Water.

VICHY-CELESTINS

And the other State Springs of Vichy.

¶ This Natural Alkaline Mineral Water may be prescribed with absolute confidence with regard to its purity and natural condition. It is bottled at the Springs under the most careful supervision, and to ensure fresh supplies is imported with regular frequency.

¶ The VICHY WATERS, being almost devoid of Sulphates, are most agreeable to the taste, and are daily relied upon by Physicians the world over in the treatment of Gout and Rheumatism and for Affections of the Liver, Stomach, etc.

NATURAL VICHY SALTS for Drinking and Baths.
VICHY DIGESTIVE PASTILLES prepared with Natural Vichy Salts.

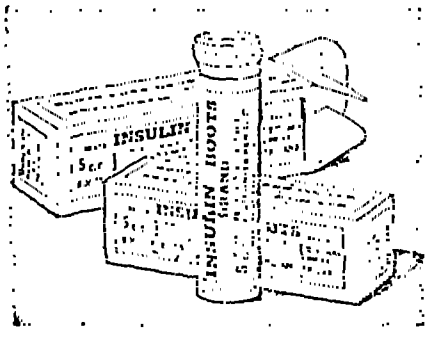
INSULIN (BOOTS)

INSULIN (BOOTS) Is prepared In the Laboratorles of Boots Pure Drug Company Ltd., under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.



It is made from selected ox pancreas which is subject to the strictest examination before use.

The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out.

Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility—these tests being carried out both before and after filling into ampoules. A sample of each batch, together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

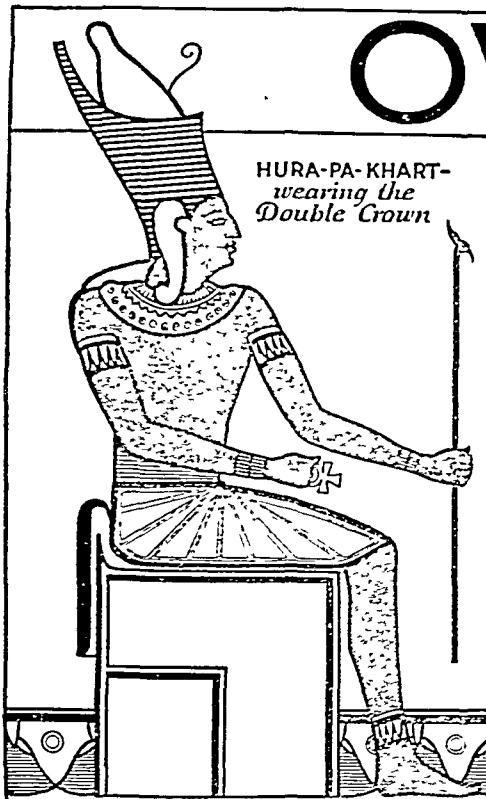
Made entirely from English Beef

The 'Allenburys' Beef Juice is prepared from prime, lean beef by a special process which conserves all the nutritive constituents and the vitamins in a natural, unaltered and assimilable form. The juice of the fresh beef is extracted under pressure and concentrated in vacuo, a low temperature being maintained throughout the process to ensure that the albumens of the beef are not coagulated.



Literature and clinical sample will be sent on application to members of the medical profession.

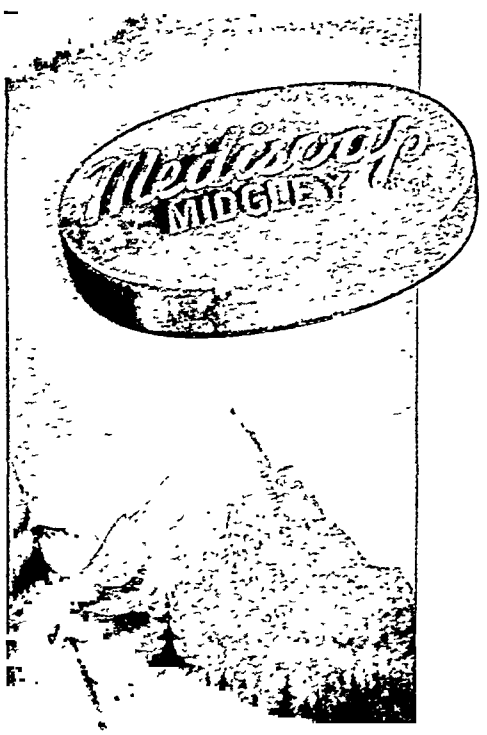
OVALTINE

HURA-PA-KHART—
wearing the Double Crown

FOR HEALTHY NUTRITION.

In every condition in which the need of a nutritious and easily digested food is indicated the advantages of "Ovaltine" are definite and many. In no case need the physician hesitate to order its liberal use.



"Ovaltine" is a highly concentrated extraction of malt, milk, and eggs. It is almost completely absorbed by the system, and because of its complete absorption, and because it is a form of nourishment complete in every respect, "Ovaltine" tones, strengthens, reinforces, and reinvigorates the whole body.

"Ovaltine" is purin-free. Its use neither aggravates the tendency to arterio-sclerosis nor favours the accumulation of uric acid in the system. This delicious food beverage sustains life ideally by promoting the healthy activity of the bodily functions.

A liberal supply for clinical trial sent free on request.

'PANOPEPTON'

LEAN BEEF—the entire group of nitrogenous substances, those natively soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, with the natural savoury extractives and minerals.

ENTIRE WHEAT GRAIN—the peculiar complex of nitrogenous substances, those naturally soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, the farinaceous substance converted into dextrin and maltose, and with the associated savoury constituents and minerals.

Of the beef nothing is excluded but the indigestible connective tissue and lipoid. Of the wheat nothing is excluded but the insoluble inert cellulose and silica of the shell of the grain.

'Panopepton' is of a uniform standardized composition; it is highly agreeable; requires no preparation. It is a potent restorative and emergency food in serious straits; a fortunate recourse for the invalid.

Supplied in 12-oz. bottles.

Roboleine

THE FOOD THAT BUILDS THE BODY

A POWERFUL reconstructive food that can be administered in all conditions, even those in which ordinary concentrated feeding and tonics are not supported, must fill an important place in therapeutics. Such a product is found in "Roboleine," which has been before the Medical Profession for nearly 25 years.

Bone-Marrow in Anaemia from Haemorrhage.

W. Borchardt (Deut. med. Woch., March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib marrow, others with marrow from the long bones. Control animals received a corresponding amount of either fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the red rib marrow showed a definite increase in weight, and their haemoglobin formation was more rapid than that of the other. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1.4 mg. per cent. The result was similar but more striking, the dogs receiving the rib marrow regaining their haemoglobin far more quickly than the others.

—*Vide* B.M.J., May 3rd, 1930.

"ROBOLEINE" contains the Marrow from the long bones, the RED MARROW OR JUICE FROM RIB BONES OF OXEN, together with Egg Yolk and a specially prepared Extract of Malt.

This is the original formula, and it may be of interest to note how closely it conformed to the latest requirements of modern research. This formula, however, has been developed in the light of clinical experience, and the vitamin content has been reinforced by the addition of our "Vitad," which is the unsaponifiable fraction of Cod Liver Oil.

ROBOLEINE may be taken by itself, or mixed with water, milk, porridge, or tea, and spread on dry biscuit forms a nourishing and stimulating "snack" lunch for children or adults.

INDICATIONS:—Rickets, Phthisis, Anaemia, Leukemia, Lymphadenoma, etc., and in those cases in which a debilitated stomach has rendered convalescence slow and difficult.

TESTING SAMPLE.

IN DISEASES OF THE SIGMOID, RECTUM & ANUS

WHERE there is irritation or obstruction in the large bowel, there is need for a soft formed, yielding faecal mass.

In these cases 'Petrolagar' is invaluable because:—

1. It permeates the faecal mass, rendering it soft and easily passed.
2. It provides comfortable elimination without strain, reducing congestion in the Haemorrhoidal veins.
3. It contains no irritant properties and is not habit forming.

'Petrolagar' is 65% pure liquid paraffin emulsified with agar-agar, and may be prescribed with confidence. It is sold under the trade name 'Petrolagar' Brand Paraffin Emulsion.

Interesting literature and liberal specimen sent free on request.

Local Anæsthesia in Surgical Practice

OVARIAN CYST

Typical Case.

Operation: Hysterectomy; Bilateral Salpingectomy; Right Oophorectomy; Appendectomy.

Mrs. W. F. A., aged 44 years.

Anaesthesia: Local infiltration; pelvic splanchnic.

Anaesthesia and Operative Technique: A mid-line infiltration was made using 150 c.c. Novocain-Adrenaline solution, and the abdomen was opened with a 10 cm. incision. The cyst which presented was punctured with a large trocar. By means of suction 6,000 c.c. of brown opaque thick fluid was aspirated so that the partially collapsed tumour could be drawn through the wound. It was found to take origin in the right ovary, which was removed along with both tubes and the uterus, as the malignant character of the cyst was noted on examination. Appendicectomy was also performed. All raw surfaces were peritonized, and the wound was closed without drainage.—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Alternative Methods in Prophylaxis and Treatment of

CORYZA

DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients.

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat). For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

(*Æsculapius*).

The prophylaxis of COMMON COLD

In the prevention of Common Cold, Evans' "Common Cold and Anti-Catarrh" Vaccine has been used for many years with very satisfactory results. Experience has shown that the best results are obtained if the vaccine course of three graduated doses is commenced some weeks before the season when the patient is liable to infection. In very susceptible cases further doses of 1 c.c. at monthly intervals should be given.

EVANS' COMMON COLD VACCINE No. 3

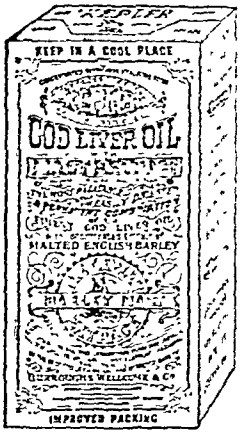
(ANTI-CATARRH VACCINE)

This has been specially evolved for prophylaxis. It is a mixed vaccine, prepared from strains isolated from actual cases.

Each c.c. contains—

M. Catarrhalis	...	...	200 mills
Pneumococci	...	...	200 „
Streptococci	...	...	200 „
B. Friedlander	...	...	100 „
B. Septus	...	...	100 „
Staphylococci	...	...	200 „
M. Tetragonus	...	...	100 „
B. Influenza	...	...	100 „

Issued in 1 c.c. ampoules, and 5 c.c., 10 c.c., and 25 c.c. rubber-capped bottles, and in boxes of graduated doses.



Obtainable from all leading pharmacists, and from
EVANS' BIOLOGICAL INSTITUTE, Higher Runcorn, Cheshire.

Hypodermic Medication with "Azoule" Solutions

"Azoule" Hypodermic products are permanent sterile solutions prepared from standardized drugs of the highest purity and are intended for subcutaneous, intramuscular, and intravenous injections.

The "Apyrogen" Distilled Water used in the preparation of "Azoule" Solutions is rendered absolutely free from toxins by means of a special process of re-distillation.

Each dose is enclosed in a sterile, hermetically-sealed ampoule of Jena glass. This glass is alkali-free and, owing to its property of absorbing actinic light rays, is specially suitable for the preservation of sterilized solutions.

A descriptive leaflet containing the latest list of "Azoule" Solutions will be sent post free on application.

Observations
ON
THE TREATMENT OF SEPTICAEMIA*
BY

SIR THOMAS HORDER, Bt., M.D.
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL

It is not easy to define the condition known as septicaemia, but the most satisfactory description is: a general infection associated with bacteria in the blood, and their multiplication there. The temporary bacteriaemia which appears in the course of pneumonia, typhoid fever, and other such infections may be excluded from the discussion, together with terminal and agonal conditions, and septic endocarditis, which is a special variety of focal sepsis associated with an overflow of bacteria from the endocardial lesion. On the other hand, bacteria may not be found in the blood for one or more of several reasons, and yet a case may be septicaemic; the concept of septicaemia is therefore essentially clinical rather than bacteriological. To escape some of these difficulties changes in terminology have been suggested. Libman declines to use the term septicaemia, but proposes no substitute; Ryle suggests "streptococcal fever" and "staphylococcal fever," and there is much to be said for this innovation. Since the problem centres round a general infection by the two common pyogenic organisms, *Streptococcus pyogenes* and *Staphylococcus aureus*, I suggest that the discussion may well be limited to these.

With the recognition of the nature of the disease the earliest efforts lay in the direction of expectant measures. Then came efforts at chemotherapy, the use of mercury perchloride intravenously being the chief of these, but such crude chemicals as carbolic acid and formalin were also tried. Failures, some disasters, and the arrival of immunology, led to bacteriotherapy—first serums, then vaccines, then sensitized vaccines, and lastly immunotransfusions. Disappointments followed, and there was a swing back of the pendulum to chemotherapy. In the meantime, measures based on protein and chemical "shock" were introduced, and are still on trial. Finally, expectant treatment has again been emphasized, as being the main standby in the majority of cases. The great lack of uniformity in practice demonstrates the absence of convincing methods of therapy.

EXPECTANT THERAPY

Expectant measures aim at getting control of the disease, rather than "curing" it; even to-day we do not "cure" tuberculosis, we "control" it. The methods of control should be instituted at the earliest possible moment, and should be exploited to the full. It can scarcely be doubted that, taken together, they are of greater service to the patient than any "specific" remedy as yet known. If it is possible to give "institutional" rather than "home" treatment, this should be undertaken. Comprised under this heading are rest and fresh air; the patient should be treated in the open air whenever possible. Food should not be stinted, but be given up to the limit of the digestive capacity, and water should be taken in abundance. Alcohol is of service, particularly in patients who have been accustomed to it previously.

Other factors in the treatment include: sunshine, both natural and artificial; eliminative measures for bowels and skin, such as hydrotherapy; the administration of alkalis and glucose to combat acidosis; haematinic drugs to control anaemia; and nucleic acid with other leucocytic stimulants. A useful formula for intramuscular injection is: sodium cacodylate 1 to 3 grains in 20 minims of a saturated solution of nucleic acid; this may be injected once or twice in the twenty-four hours. Sleep must be secured, and pain relieved. Paget, who suffered from an attack of septicaemia, paid a glowing tribute to morphine. Pyrexia is to be controlled by ample ventilation of the skin and hydrotherapy. Good nursing is imperative, and the personality of the doctor, who should be encouraging, resourceful, and confident, is a great adjunct to success. Although expectant measures lack the dramatic element, and are consequently not popular, they are the only ones which have stood the test of experience.

SPECIFIC TREATMENT

Bacteriotherapy.—Serums have been disappointing, but the theory is so attractive that they are still the most popular remedy on specific lines. "Bactericidal" serums were anti-endotoxic in the main, but their content in antibody has never been such as to satisfy the immunologist. Recently, efforts have been directed towards the production of anti-exotoxic serums; and these "antitoxic" serums appear already to be more helpful, especially in the case of the streptococcus. They should be used early and in adequate doses. "Sensitized" vaccines (Besredka) seem to be successful in some acute streptococcal cases. Antigen therapy is of little or no proved service; "immunogens," which are ecto-antigens, have scarcely yet had a good trial. Immuno-transfusions have been on trial now for ten years, and it is doubtful if any good effects reported are due to a specific increase in the bactericidal powers of the blood so much as to non-specific aid given by the transfusion. So long as the immunological factors in the interaction between the tissues and the infecting organism are still so largely undetermined, there must needs be doubt as to the best type of specific remedy, but in general infections (as compared with local) there is an *a priori* bias in favour of passive, rather than active, methods. Finally, bacteriophages are on trial and have been commercialized.

Chemotherapy.—During and immediately after the war the chlorine group was in favour. More recently mercurial treatment has been revived, and especially in combination with aniline dyes. The favourite at present is mercurochrome, 10 to 15 c.cm. of a 0.5 per cent. solution being given by the intravenous route on alternate, or even on successive, days. The dangers are thrombosis and renal insufficiency, but successes are recorded from time to time, which may be due to "chemical shock." Novarsenobillon and other salvarsan equivalents have been used freely, following their success in syphilis. The ideal blood disinfectant must diffuse rapidly and widely; it must be non-toxic to the tissue cells, and must retain its bactericidal power over a lengthy period. We need not despair of finding something even better than mercurochrome.

Blood Transfusions.—These are definitely useful, but chiefly to combat the anaemia due to haemolysis.

Shock Therapy.—As regards protein shock, the indications are difficult; probably it should be reserved for the later stages of the disease, and, even then, it should be adopted with caution. Chemical shock treatment is best left to those who understand the teaching upon which the practice is based.

Surgery.—In all cases close co-operation between physician and surgeon is essential. Early in the case this applies especially to the focus of primary infection, if this is known; later, and throughout the course of the disease, it is concerned with the formation of metastases—whether in or around joints, bones, serous membranes, or

* A synopsis of the remarks made in opening a discussion at a joint meeting of the Sections of Medicine and Surgery at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

solid organs Thorough survey of the patient, almost daily, for these metastases must be made. Effusions are to be dealt with by aspiration for preference, but if this is unsuccessful, then incision and drainage become necessary. Great exercise of judgement is required at both these stages of the disease. Surgery is indicated more often, and more early, in staphylococcal than in streptococcal infections. The favourite sites for staphylococcal metastases should be passed in review again and again.

General Remarks

The individual case is to be treated on its merits, due consideration being given meanwhile to any general specific remedy offered by the immunologist, and applicable to the particular infection concerned. The physician should work hand in hand with the bacteriologist, but should not take the cue entirely from him in matters of treatment. Close liaison with the surgeon is a *sine qua non* for success. Expectant measures should be mobilized promptly and thoroughly. All the therapeutic "eggs" should never be put into one basket. A plan of campaign appropriate to the case in point should be decided upon and steadily continued, and the patient should not be disturbed by too many treatments. Panic on the part of the friends is a frequent deterrent, but is pardonable; panic on the part of the medical adviser is sometimes fatal and is unforgivable.

SURGICAL ASPECTS OF SEPTICAEMIA *

BY

D. P. D. WILKIE, M.D., Ch.M., F.R.C.S.

PROFESSOR OF SURGERY IN THE UNIVERSITY OF EDINBURGH

The question under discussion to-day, whilst of vital importance and wide interest, is, at the same time, one on which fruitful debate is difficult. Many of us have had considerable experience, of an occasional and isolated nature, of cases of septicaemia; few have had the opportunity of treating a series on truly scientific lines. The features peculiar to the individual case, the intermittent and irregular incidence of cases, our own changing ideas of the value of certain lines of treatment, all tend to render judgement difficult. Further, we are so apt to enthrone in the sunshine of our memory the apparently striking success, and to allow the many failures to slip into the quiet shadows of forgetfulness.

The surgeon may be called on to deal with septicaemia under three sets of circumstances:

(1) Following an infected accidental wound;

(2) Accompanying an idiopathic infection, such as acute osteomyelitis, cellulitis, or phlebitis;

(3) Following operation on an infected area.

In (1) and (2) active surgical intervention may be called for, but nicety of judgement is necessary in determining how much must be done, and when. In many cases it will be found that active surgery must be held in restraint until such time as the indications for intervention have become abundantly clear—in other words, the knife may be a lethal weapon if prematurely or incautiously applied (for example, in the infected puncture wound too hasty incision may induce septicaemia by bursting imperfectly formed natural barriers and throwing open to micro-organisms a pathway into the blood stream). Respect for, and aid to, the formation of such barriers are essential criteria of the successful treatment of such infected wounds.

In the common streptococcal infected wound of the finger or hand, with rapidly developing lymphangitis, the judicious use of passive congestion and administration of antiserum should always precede any treatment by incision. The value of Bier's passive congestion is not sufficiently recognized. Rightly used, I believe that it is a very real help in preventing and limiting blood infection. Bier laid no claim to be the originator of the idea of passive venous congestion as a therapeutic measure. He has, however, fully earned lasting credit for demonstrating how by this means a local infection, which was tending to invade the blood stream, might be hemmed in and held up until such time as local defences had been mobilized, and the general protective mechanism had been stirred to action. Rightly applied, a Bier's bandage will always relieve pain. If the pain persists or is increased, the bandage should be removed and reapplied more lightly. It should be worn for twenty-two hours out of the twenty-four.

Many deaths have resulted from a precipitate use of the bistoury, no time having been allowed for a leucocytic encirclement to develop and a natural localization of the contest to occur. Only when dangerous tension has arisen, or dead or moribund cells have accumulated in the shape of pus, can incision be helpful.

In certain tissues, such as bone and deep cellular planes, where rigid walls prevent the deployment of natural resistant forces, early incision may be of the utmost value in permitting expansion and the entrance of protective elements. Total excision of the focus—for example, in anthrax pustule, in carbuncle, and in the very earliest stages of an infected punctured wound—may sometimes be justified; as a general rule, however, surgery must exercise a watching brief, prepared to step in when, and only when, nature cries for help.

When we consider the various means by which the patient's resistance to the invading germ may be supplemented we turn first to antiserums. Varied opinions will doubtless be expressed as to the value of anti-streptococcal serum. As with anti-tetanic serum, large doses (60 c.cm.) must be given early and repeated daily. My experience has been that it is in the *very earliest stages* of the general infection, before cellular damage to the organs has occurred, that the help from passive immunity is great and real. I have no hesitation in placing it first in importance, just as I believe it should take precedence in time of all other measures.

Copious quantities of fluid must be given, usually by mouth. In exceptional cases where vomiting occurs fluid must be given rectally or subcutaneously. If an abscess develops at the site of subcutaneous injection, it will be a matter for rejoicing. With the fluid, alkalis and glucose must be freely given. As a rule they are both welcomed by the patient, which is significant.

Immuno-transfusion should certainly be considered in the weakly patient, and I have seen it followed by remarkable betterment in a case in which blood infection had supervened in a feeble and anaemic patient. How much of the benefit was due to the introduction of specific antibodies and how much simply to the supply of healthy blood was impossible to determine.

The production of a really efficient anti-staphylococcal serum is a real need, and I trust that the antitoxic serum now on trial may prove to have for the human subject as true and specific a protective action as it has been proved to possess for animals.

The use of vaccines in a fulminating blood infection I have always regarded with scepticism and, along with protein shock therapy, I have left to those who can visualize their action and believe in their efficacy. Specialized vaccines have given favourable results in some hands, and they undoubtedly deserve an extended trial.

* Introductory remarks in a joint discussion in the Sections of Surgery and Pathology at the Annual Meeting of the British Medical Association, Edinburgh, 1931.

The intramuscular injection of nuclein preparations to induce a leucocytosis, and of various colloidal preparations, I have found to be successful only when an abscess has formed at the site of injection. This development of a "fixation abscess," an old time method of treatment, is often the signal of improvement, and is a welcome complication in a critical case

The search for a therapia sterilisans magna—some chemical substance with an affinity for the germ, yet relatively harmless to the host—cannot yet be said to be successful. Intravenous injections of cusol, of mercurochrome, of collosol argentum, and of certain dyes have each given apparently favourable results in isolated cases Personally I cannot claim to have seen a cure by the injection of any of these chemical substances in a case where other factors could be ruled out.

A constant watch must be kept for abscess formation, be it in deep cellular planes, in joints, or in the pleural cavity. In the later stages of a septicaemia purulent collections may develop most insidiously, and their timely evacuation may turn the scale They may very readily be missed if a systematic examination for them be not made repeatedly

In a few cases the question of amputation of a limb may have to be considered I believe that amputation is rarely justified except in protracted cases where the infection involves a bone or joint, where adequate drainage cannot be effected, and where the patient's strength is ebbing

Whilst vaccines, in my experience, have a very doubtful place in the treatment of established septicaemia, they have a real value when used for preliminary and prophylactic immunization in cases where operation for the removal of a large ulcerating growth may permit of a blood infection It has been our practice for over twenty years to give a preliminary course of *B coli* and streptococcus vaccine in operations for removal of growths of the lower bowel, and in particular the rectum In such operations many infected lymph channels must of necessity be divided, large raw areas are usually left, and the risk of generalized infection is obvious Preliminary vaccine treatment, particularly if followed by a pre operative injection of nuclein to stimulate a leucocytosis, was shown experimentally to increase resistance, and in practice it has proved effective

My practice is to give *B coli*, 50 millions, and streptococcus, 10 millions, ten days, and again three days, before operation, and on the night preceding operation to give 5 c cm of 5 per cent sodium nucleinate intramuscularly The patient thus comes on the table with defensive forces warned, and with a slight leucocytosis (10,000–14 000 Since using this preliminary treatment I have lost no case from general sepsis, although local infection of a gross nature has supervened in a number of cases

With a feeling of security against a general infection, local sepsis after an operation for cancer may be regarded almost as a blessing

In the treatment of septicaemia the future lies largely in the hands of the bacteriologist. In the clinical field I should sum up the position by saying that the physician must think surgically, and the surgeon must cultivate the restraint of the physician.

DIET AS A PROPHYLACTIC AGENT AGAINST PUERPERAL SEPSIS

With Special Reference to Vitamin A as an Anti-infective Agent

BY

H. N. GREEN, M.D., M.Sc.,

D. PINDAR, M.B., Ch.B. G. DAVIS, M.B., F.R.C.S.Ed.

AND

E. MELLANBY, M.D., F.R.C.P., F.R.S.

In a previous paper (1929) on the treatment of puerperal septicaemia with preparations containing vitamin A we stated that an investigation was also being made into the possible prophylactic effect of such preparations against puerperal sepsis We argued that if vitamin A had even a slight therapeutic effect in such a virulent infection as septicaemia it should be of much greater value as a prophylactic agent It seemed possible that in the administration of vitamin A prior to labour we might have a valuable auxiliary method which would supply a missing factor so apparent in some cases even where every precaution against sepsis has been taken.

Experimental work on young animals suggested that vitamin A and carotene might well be described as "anti-infective" in their action, because when absent from or deficient in the diet, multiple infective foci develop, resulting in death unless the deficiency is made good (Green and Mellanby, 1928, 1930) The preventive and curative actions of vitamin A and carotene in the autogenous sepsis of the animals were equally great. It was obviously desirable to see whether these substances played any similar part in controlling the resistance of the human body to sepsis This seemed possible, for the septic lesions which develop autogenously in animals on a vitamin A deficient diet are also commonly found in human beings These include septic nasal sinuses, a catarrhal condition of nose and throat and respiratory passages, middle ear disease, broncho-pneumonia, pyelitis, and a septic condition of the genito-urinary tract There is also reason to believe that the diet of many individuals in this country is deficient in vitamin A, the main sources of which are found in the more expensive foods—for example, milk, butter, eggs, and certain vegetables, while it is almost completely absent from cereals and cereal products and many other extensively eaten foods

A study of the prophylactic action of vitamin A against puerperal sepsis in women suggested itself as a promising method of testing the clinical significance of the animal experiments The duty of the maternal organism during pregnancy is to supply all the substances necessary for the growth of the embryo These substances she either gets directly from her food, synthesizes them from the ingested foodstuffs, or, when these sources are insufficient, she supplies them from her own body stores as long as they are available. Many substances cannot be synthesized by the body, and must therefore come directly from her food or from her depots replenished by food Now the body has a great capacity for storing vitamin A, especially in the liver. This store has its origin in the vitamin A, and most probably also in the carotene, of the food eaten (Moore). If the diet is deficient in these factors, as is probably the case in many individuals, the liver stores of vitamin A may be small, even at the beginning of pregnancy. The demands of the growing foetus will make these reserves still smaller, for, in addition to the supplies necessary for actual growth and metabolism, the foetus demands a reserve of vitamin A for its own liver (H. N. Green examined eight foetal livers and found that six of them contained vitamin A in varying quantities.) These facts indicate that many women at childbirth will be deprived of most of their reserves of vitamin A and, if the animal experiments have any meaning in terms of the human subject, they will have less resistance to the invasion of pathogenic organisms at the time of parturition.

Apart from this evidence, however, there are other direct indications that women during pregnancy are specially liable to develop gross signs of vitamin A deficiency. Thus Birnbacher noticed that hemeralopia arising from lack of fat-soluble vitamins in the after-war years in Vienna was much more frequent during pregnancy, particularly towards the end of term and in women bearing heavy children.

Two other observations suggested the need for this investigation:

1 The infective foci found in animals following vitamin A deficiency are particularly prominent in relation to squamous, columnar, and ciliated epithelium, and this is of special importance in the present instance, since puerperal sepsis is primarily an invasion of the epithelium of the generative organs by pathogenic bacteria.

2 H N. Green has found that if rats, when pregnant, are given diets complete except for vitamin A, a large proportion of them ultimately develop chronic sepsis of the generative tract, while, on a complete diet at this time, control rats after pregnancy are unaffected in this respect. Nor are virgin rats so liable to develop this form of sepsis, even on a vitamin A deficient diet.

The usually accepted explanation of the frequency with which puerperal sepsis develops is that women during labour are more exposed to external infection. This is undoubtedly true, and might be accepted as a full explanation if all straightforward parturitions without intervention, or even parturitions carried out by the most complete asepsis practicable, escaped this complication. Unfortunately modern obstetrical technique has not had the complete success which would be expected if this were the whole explanation

It seemed to us that the margin of safety as regards sepsis in childbirth must often be very narrow, and it was with the object of attempting to increase this margin and, at the same time, of testing our hypothesis based on the foregoing evidence, that the following inquiry was made. (A brief account of this work at an earlier stage was given by one of us (E M) at the Public Health Congress, 1930)

Method of Investigation

About 600 women were involved in the present investigation All cases not delivered in hospital were rejected from the series, so that a total of 275 women treated with the vitamin preparation and 275 untreated to serve as controls remain for analysis

Pregnant women attending the ante-natal clinic were instructed to take half a teaspoonful of the preparation daily, commencing one month previous to the calculated day of labour A fortnight's supply was given at a time Theoretically, therefore, 1½ oz of the vitamin preparation radiostoleum an amount equivalent in vitamins A and D roughly to 30 oz of a good cod liver oil, should have been taken during the month The investigation began in November, 1928 The first seventy-six cases prior to June, 1929, were given the preparation for only fourteen days before delivery It was, however, continued for the first seven days of the puerperium It was then decided that a more logical procedure would probably be to begin the administration earlier and thus build up a larger reserve at the time of labour. In these cases none was given after admission to hospital. The cases were in no way selected; the first patient was given the preparation and the next due for delivery about the same time was indexed as a control. The vitamin and control groups were thus equally distributed in point of time; seasonal and epidemic or contagious influences predisposing to infection therefore tend to be equal in the two groups. It was considered that this method would give more uniform conditions than treating random groups of ante-natal patients with the preparation and considering all the remaining untreated ante-natal cases as controls.

Of the cases, 440 attended the Jessop Hospital ante natal clinic and were delivered at this hospital, 110 attended the municipal ante-natal clinic and were delivered at the Nether Edge municipal hospital. The two series have been classified together, as the number of cases and the incidence of sepsis in the smaller group is too small to warrant analysis.

Radiostoleum, the vitamin preparation used in this investigation, contains sources of vitamins A and D dissolved in a neutral oil; 1 c.cm. of the preparation contains 150 blue units (Carr and Price) of vitamin A and 5,000 units of vitamin D in the form of irradiated ergosterol. British Drug Houses, Ltd., have kindly supplied the whole amount used in this investigation

Results

In Table I the results are classified on the basis of the B.M.A. standard for puerperal morbidity—that is, all cases with two rises of temperature of 100° F or over between the end of the first and the end of the eighth day after delivery. This standard was adopted since it is the one in use for statistical purposes at the hospitals concerned, and thus allowed of a direct comparison between the figures in the experimental series and those obtained in previous years at the same hospital.

It will be seen from this table that the number of primiparae in each group was almost equal, as was the

Table I.—*Effect of giving Vitamins A and D before Puerperium on Incidence of Puerperal Sepsis*

* Temperature of 99° F or over on ... until discharge—not ... morbidity

which had some form of manual or instrumental intervention The number of complicating factors during labour tends also to be equally distributed in the two groups In the vitamin group there were only three morbid cases on the B M A standard, an incidence of 1 09 per cent In the control group there were thirteen morbid cases, an incidence of 4 73 per cent The difference, 3 64 per cent, is over twice the standard error (1 43) and is therefore statistically significant It is worthy of note that in the five cases of Caesarean section, one of accidental haemorrhage, and one of placenta praevia included in the control group, no morbid case occurred

In Table II it will be seen that the morbidity rate for the two groups combined was much lower than that of previous years for the whole of the ante natal patients

TABLE II—*Morbidity Rate in Ante natal Cases delivered at the Jessop Hospital in the Three Years Prior to which Present Investigation was commenced as compared with that in Cases covered by Present Investigation*

Year	No of Deliveries	B M A Morbid Cases	Maternal Mortality
		Per cent	Per cent
1925	Ante natal 585	5 0	1 0
	Total cases 750	9 6	2 9
1927	Ante natal 553	8 1	1 1
	Total cases ... 812	12 4	2 6
1928	Ante natal 652	7 3	1 5
	Total cases 953	9 9	2 6
Cases included in investigation during period 1 November 1930–June 1931			
Total cases Jessop Hospital	410	3 4	0 3
Vitamin group	294	1 0	0 0
Control group	230	5 8	0 5
Total cases Jessop and Municipal Hospitals	550	2 9	0 2
Vitamin group	275	1 1	0 0
Control group ...	275	4 7	0 4

The control group for the Jessop Hospital shows a morbidity rate of 5 8 per cent, compared with an average morbidity of 6 8 per cent for the three years previous to which this investigation was begun The morbidity rate for ante natal patients was much lower than that of hospital cases in general, and appears to be improving The vitamin group delivered at the Jessop Hospital shows a morbidity rate of 1 per cent, which, compared with those of the control group (5 8 per cent) and of the ante-natal cases over the previous three years (5 per cent, 8 1 per cent, and 7 3 per cent), shows a significant difference

In Table I all cases which have shown any degree of puerperal pyrexia other than those of the B M A standard have also been tabulated Obviously many of these cases were not septic, since a rise of temperature which is not maintained can arise from other causes, but this type of case should tend to be equally distributed in the two groups, as the figures in Table IV indicate The total number of pyrexial cases in the vitamin group was 56, an incidence of 20 4 per cent, and in the control group 98, an incidence of 35 6 per cent The difference of 15 2 per cent is almost four times the standard error (3 83), and is therefore significant It may be noted here that an analysis of the results at various stages of the investigation has shown the same relative difference in the incidence of pyrexia at each analysis

In the total 550 cases there was one maternal death

The classification of morbidity on any arbitrary standard such as that of the B M A, though useful, gives an incomplete summation of the incidence of sepsis, particularly where, as in the B M A classification, no note is taken of septic cases occurring after the eighth day The notifiable standard under the Public Health Regulations overcomes this difficulty to some extent, it includes cases in which, on the bi daily chart, a temperature of 100 4° F or over occurs twice in three successive readings during the twenty one days following delivery Using this standard, as seen in Table III, there were 11 morbid cases in the vitamin group, and 13 in the control group

TABLE III—*Morbid Cases in Two Groups classified on Notifiable Standard*

	No of Cases	No Morbid	Percentage Morbid
Total	550	25	4 7
Vitamin group	275	11	4 0
Control group	275	13	5 0

If we had adopted this standard alone without further analysis, and assessed our conclusion on it, we should have concluded that the vitamin treatment had little or no effect on the incidence of sepsis in the puerperium On the other hand, if we compared the incidence on this standard with that on the B M A standard it might appear that prophylaxis with vitamin A had delayed the onset of sepsis until a later stage in the puerperium

It is possible that the vitamin reserve built up at the time of labour had been exhausted during labour and the first week of lactation, and so the resistance of the vitamin group at this stage fell nearer to that of the control group This, however, is conjecture, and it seemed that a comparison of the clinical severity of the septic cases in the two groups would assist in arriving at some conclusion We have shown that the difference in the number of pyrexial cases is significant If, therefore the number of cases ranged according to a rough standard of clinical severity tend to be distributed in similar proportion in the two groups, this would indicate that the incidence of sepsis of a major type was significantly greater in the control group

Table IV shows that this is so for while there were 10 cases in the control group which had pyrexia lasting from one to three weeks, there were only 4 of this type

TABLE IV—*Cases arranged according to severity, as indicated by Duration of Pyrexia*

	Vitamin Group		Control Group
Number of cases ...	275	... ...	275
Pyrexial cases	56	... ...	98

*Temperature raised to 99° F or above for one to three weeks.
†Temperature raised to 99° F or above for two to six days with definite local infection
‡Temperature raised on more than one occasion to 99° F or above after first day but no local infection definitely diagnosed excluding septic peritoneum
§Temperature raised only once after first day to 99° F or above

in the vitamin group and the distribution according to clinical severity is practically identical throughout All the cases under the first two headings had some definite

local infection There were 12 of this type in the vitamin group and 26 in the control group. It appears, therefore, that the smaller incidence of pyrexial cases in the vitamin group does indicate a smaller incidence of sepsis as compared with the control group.

Effect of Intervention

Table V shows that 26 cases in the vitamin group and 27 in the control group were subjected to some form of manual or instrumental intervention of a major kind.

TABLE V.—*Incidence of Sepsis in Cases submitted to Intervention*

	Vitamins A and D	Controls
Number of cases	26	27
Morbid cases (B.M.A.)	2	3
Pyrexial cases	7	15
Severe	0	3
Less severe	0	3
Moderate	4	5
Mild	3	4

These accounted for 2 morbid cases (B.M.A.) of the 3 in the vitamin group, and 3 morbid of 13 in the control group None of the vitamin group with intervention developed any local infection, while 6 of the control group with intervention had local infection—3 classified as severe and 3 as less severe There were in all 7 pyrexial cases in the vitamin group with intervention, and 15 in the control group with intervention.

Infantile Morbidity

There is nothing significant in the incidence of sepsis in the infants born in the two groups, nor was any difference observed in the progress of the infants during the short period they were in hospital.

Discussion

We believe that these results indicate that the administration of vitamin A during the last month of pregnancy has diminished the liability to a morbid puerperium. It seems that the incidence of sepsis, particularly in the early period of the puerperium, in which the most dangerous types of sepsis are liable to arise, has been lowered by increasing the vitamin A intake. It was not, of course, to be expected that this would cause a complete disappearance of sepsis Probably no measure which increases the systemic or local resistance will prevent the development of pyrexia if the bacterial invasion is sufficiently great An increased resistance should result in a decreased number of cases of puerperal pyrexia, and a decrease in clinical severity and duration of infection in those cases infected This tendency can be observed in the difference between the treated and non treated cases in this series. It must be emphasized also that there was no certainty that all the women ordered to take the vitamin preparation actually took it Some individuals found it unpleasant, and it is probable that at least a small proportion of cases did not take the preparation This possibility makes the positive interpretation of our results more likely.

The preparation given contained a fair amount of vitamin D as well as vitamin A. On experimental grounds we are inclined to believe that vitamin D has little anti-infective action; it was thought, however, that it might prove of significance in connexion with other obstetric difficulties, such as uterine inertia, but on this point we have obtained no evidence. The possibility cannot be denied, however, that the results described may be due, in part at least, to the presence of increased vitamin D in the diet. To ensure a normal calcium metabolism it is essential that the diet of the pregnant woman should contain some source of vitamin D. Now vitamin D is often closely associated with vitamin A in nature, although not so widely distributed, so that whether the ordinary food contains sufficient vitamin D, or whether it is given as a supplement such as cod-liver oil, a good supply of vitamin A is likely to be assured.

Our experimental and clinical results indicate that an adequate supply of vitamin A must be given to the pregnant woman. It should be the aim of all concerned with ante-natal welfare to see that the diet is rich in natural sources of vitamin A. Milk, egg yolk, green vegetables, carrots, and butter should be taken unsparingly, as long as over-eating is avoided by reduction in the cereal and meat content of the diet to a level where a healthy appetite is developed. Mammalian liver is an excellent source of vitamin A, and should be included in the diet at least once weekly unless otherwise contraindicated If a well-varied natural diet of this kind is taken, an adequate supply of the other important nutritional factors is assured. These include the other known accessory food factors—vitamins B (complex), C, and D—together with the inorganic elements—calcium, phosphorus, iron, copper, manganese, and iodine—all essential for the pregnant woman.

Where this complete diet cannot be taken for economic or other reasons, it should be supplemented by some preparation rich in vitamins A and D. Cod-liver oil is the cheapest source, but where a dislike to this oil exists a reliable commercial preparation rich in these vitamins is indicated. The best line of action is undoubtedly to regulate the diet during pregnancy and lactation along the lines indicated, and, if this is done, there may be no need for supplementary rich sources of the fat soluble vitamins. Where social conditions are poor, however, or where the course of labour makes the occurrence of infection probable, some preparations of this kind should be of value as a prophylactic measure. The same course of dietary should also be adopted throughout the puerperium and lactation so as further to increase the resistance

Summary

1. This investigation relates to 550 pregnant women attending the out-patient department of the ante natal clinics of Sheffield, and subsequently delivered in hospital

2. Alternate women were given an extra supply of vitamins A and D during the later weeks of pregnancy (usually for one month, but in some cases for a fortnight before delivery). Thus, 275 women received the vitamin supplement and 275 women acted as controls

3. Of the vitamin-treated cases 1.1 per cent. and of the control cases 4.7 per cent. developed the B.M.A. standard of morbidity.

4. The results classified on the basis of duration of pyrexia also suggest that the vitamin preparation increased the resistance of the puerperal women to infection

We wish to express our thanks for the facilities for carrying out this investigation offered to us by the honorary staff of the Jessop and Nether Edge Hospitals We are also greatly indebted to Dr. M. Walker for assisting us with the cases investigated at the Sheffield Ante-Natal Clinic, and to Dr. Matthew Young for examining the results statistically The expenses of this investigation have been provided by the Medical Research Council, to whom our thanks are due

PREVENTION AND CONTROL OF MEASLES, SCARLET FEVER, AND DIPHTHERIA IN INSTITUTIONS AND THE HOME *

BY

DAVID N NABARRO, M D, F R C P

DIRECTOR OF THE PATHOLOGICAL DEPARTMENT HOSPITAL FOR SICK CHILDREN GREAT ORMOND STREET

AND

A GORDON SIGNY, M R C S, L R C P

ASSISTANT PATHOLOGIST TO THE HOSPITAL

We do not intend to include in the present survey any account of the methods of isolation now practised, as these fall rather into the realms of public health We are now concerned with the recent advances in the preventive measures at our disposal for dealing with diphtheria, scarlet fever, and measles

DIPHTHERIA

The greatest advance in our knowledge of this disease came with the introduction of the Schick test This consists of the intradermic inoculation of diphtheria exotoxin so diluted that the 0 2 c cm injected contains 1 50 of a minimum dose lethal to a guinea pig of 250 grams weight (M L D) Heated toxin of similar strength is used as a control As a result of this dose, which was first recommended by Schick and has been adhered to by most workers, the community can be divided into several distinct classes

1 *Negative Reaction* —All negative reactors have been shown to have at least 1 40 of a unit of diphtheria antitoxin per c cm of blood serum This is sufficient protection against a normal infecting dose of diphtheria bacilli

2 *Positive Reaction* —When there is less than 1/40 of a unit per c cm a red, raised erythematous patch appears in about twenty four hours, is best seen at three days, and persists for a week, when a branny desquamation appears with a brown discoloration of the area Occasionally a typical positive reaction is seen within twenty four hours and disappears before three days These are probably border line cases whose blood has about 1/40 of a unit per c cm , and it will later be shown that these do not need to be immunized The control injection in these two reactions is quite negative throughout

3 *Pseudo Negative* —In this type of reaction there is an exactly similar response to the control and to the unheated toxin The reaction disappears within forty eight hours and is probably due to a sensitivity to the protein in the inoculum These are immunes

4 *Pseudo Combined Positive* —Both this and the previous type of reaction occur more commonly in convalescents from diphtheria in carriers, and in people who have been immunized In this type both the control and the test inoculations react positively The test, however, gives a much larger reaction, consisting as it does of a protein reaction, equivalent to the control injection, plus a reaction to the toxin The protein reaction fades rapidly in both injections, leaving a normal positive reading in the test It is chiefly on account of these reactions that it is essential to read the Schick test at least on two separate occasions, that is, after twenty four hours, and three days, and if there remains any doubt, again at the end of the week One is well advised to follow the rule laid down by Dudley[1]—to immunize all those who give doubtful reactions as well as the definitely positive, as diphtheria occurring in an individual who has been told he is immune is apt to cause prejudice against the methods used

About 85 per cent of infants up to 6 months are Schick immune (equivalent to the adult female Schick negative rate) Thereafter, up to 5 years of age comes the ' diphtheria period, when 90 per cent are susceptible The infants have a passive immunity transferred by the placenta and greatly increased by the colostrum (which has a higher concentration of antitoxin than the blood) and later by the milk This passive immunity can be prolonged by continued breast feeding As soon as this passive immunity is lost the children, losing their circulating antitoxin, become Schick positive As they approach the adult stage more and more people react negatively This is out of all proportion to the diphtheria case rate Therefore, it is not due to immunization by a previous attack of diphtheria, but is in all probability due to subminimal repeated infections causing a latent immunization It has been shown that in isolated communities where there has been no diphtheria for many years the Schick positive rate is inordinately high whereas in similar communities where there have been repeated outbreaks of diphtheria the Schick positives form a very low proportion There is no doubt that repeated encounters with the bacillus are sufficient to produce a degree of immunity equivalent to the Schick immune and in all probability we have to be thankful for the 3 per cent of the normal population who are virulent carriers for most of our immunity This immunity may be complete or incomplete In the latter case we have the Schick positive immunes" of Glenny, who has demonstrated the enormous difference between primary and secondary stimulation On the very first meeting with an antigen (in this case we refer to diphtheria toxin either in the form of prophylactic or the Klebs Loeffler bacillus itself) the antibody response of the individual takes a short while to show itself, is never very marked, and rapidly falls On a second meeting, however, the response is almost immediate, is very great, and remains at a permanently high level The practical value of this observation is enormous In the first place, it probably explains why about 50 per cent of diphtheria convalescents are still Schick positive They had probably never been in contact with the K L B before, and were therefore Schick-positive and developed, perhaps, severe diphtheria Their antitoxin rose during the attack, only to fall below 1/40 per c cm afterwards It is significant, however, that very few of them indeed are subject to a second attack , this is readily explained by the fact that the mere coming in contact with the organism a second time is sufficient to shoot their antitoxin titre so high as to give them a good immunity The observation receives its practical application in routine Schick-testing and immunization, as it is claimed to be unnecessary to immunize those convalescents who are Schick positive This is not a safe rule to follow without having the titre of the blood antitoxin estimated, because there is a small group of people who are naturally bad antitoxin producers this tendency appear to be familial, inasmuch as if a child acquires the same blood group as a poor antitoxin producing father he will probably inherit the defect whereas were he to follow the mother's group or be of another group he would follow the ordinary laws of the Schick reaction in the population This hereditary genetic defect of Hirszfeld is not linked to any particular blood group

Active Immunization

Many means of artificial immunization have been recommended and since the introduction of the Schick reaction it has been possible to estimate the relative merits of the methods To do this it is essential to Schick test before commencing immunization and also at intervals

* Read in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association Eastbourne, 1931

afterwards. This point must be stressed, because many references are found in the literature where the whole of the child population is regarded as being positive, and consequently not tested before immunization. Also, in several reported cases of failure of the active immunization, there is no mention of a retest after immunization, so that one is left to *assume* that the patient was immune and yet developed diphtheria. There are very few cases of failure on record where the Schick tests, the immunization, and the virulence of the K.L.B. are authentic. The following are the methods in use for obtaining active immunity:

1. Injection of (*a*) toxin, (*b*) toxin and antitoxin, (*c*) toxoid, (*d*) toxoid and antitoxin (T.A.M.), and (*e*) toxoid-antitoxin floccules (Ramon) (T.A.F.).
2. Spraying of throat with toxin and antitoxin.
3. Instilling formol-toxoid into the nose.
4. Percutaneous method of applying toxin-antitoxin.

Toxin itself is very unsafe to use, and it has been found advisable to use toxin modified by the addition of formalin (toxoid), so that it loses its toxicity without losing any of its antigenic properties. Toxoid mixed with antitoxin (T.A.M.) has been very widely used with great success both in this country and in America. Of this mixture 0.1 c.cm. is first injected intramuscularly, and if there is no reaction (sore arm or, rarely, malaise) within three days, three subsequent doses of 1 c.cm. are injected at intervals of one week.

Retests should be done as a routine a month later. About 80 per cent. of children and about 60 per cent. of adults will have become negative one month after the injections. The majority of the remainder become negative more slowly, but most are Schick-negative at the end of six months. If the Schick test has not become negative and is showing no diminution in the reaction, a further course of injections should be given, as the patient is probably a bad antitoxin producer and the type of person who, if infected, would have a severe attack of diphtheria. Even the most refractory case will respond if sufficient prophylactic is given.

More recently the floccules, produced by the addition of toxoid to antitoxin, have been shown to possess great antigenic properties. These are emulsified in saline (T.A.F.) and are injected in doses of $\frac{1}{2}$ to 1 c.cm. intramuscularly. Two injections given at a month's interval are found to raise the blood antitoxin to a higher degree than the T.A.M., and there is even less likelihood of a severe reaction.

Success has been claimed for other methods mentioned, but we have no practical experience of them. They are not claimed to be as efficient as T.A.M. or T.A.F.

When reactions after inoculations occur they are nearly always in the pseudo-combined reactors, and it is advisable when immunizing such patients to increase the doses slowly and allow longer intervals between the injections.

Results

There are two types of negative reactors—namely, natural and acquired. It is found that once a patient has become negative by natural means (clinical diphtheria or repeated subminimal infections) he has developed an antitoxin titre of about 1/20 unit per c.cm., and will probably never lose this immunity. This is borne out by the fact that the majority of the adult population (85 to 90 per cent.) is Schick-negative and remains so. Of 133 cases of natural immunes whom they retested, Parish and Okell[1] found that 1.1 per cent. had a positive reaction, and they explain these as "borderline" cases whose antitoxin fluctuates round about 1/30 to 2d/40 unit per c.cm., and who have not had a secondary antigenic stimulus. In some of these the stimulus necessary to cause a marked increase in antitoxins is so small that the Schick test dose itself is sufficient.

The figures for the acquired active immunity are not yet complete. Cooperstock[3] shows that in positive adults treated with two injections of toxoid

58 per cent. were negative after 3 weeks.
75 " " " " " 9 "
92 " " " " " 22 "

Parish and Okell[4] retested 440 children from 1 to 7 years after immunization and found that 95 per cent. of them were still negative and that the other 5 per cent. were "basally negative," that is, they rapidly became negative with a small stimulus of toxin (Schick-positive immunes of Glenny). It has been shown that a very much higher degree of immunity is acquired if after the preventive inoculation the patient has further experience of the K.L.B.: it is also an accepted fact that it is easier to immunize a Schick-positive from a herd with many immunes than with a small percentage, because this immunity indicates previous experience by the herd. It is inconceivable that even borderline cases, Schick-negative (natural or acquired), could develop an attack of clinical diphtheria, and Dudley[5] in his survey of the recorded cases decided that

"most of the reported failures occurring in Schick-negative reactors (natural) are merely sore throats with K.L.B. in them. No case of typical membrane has been reported, and it has only very rarely been thought advisable on clinical grounds to give serum. Most of these must be classed as K.L.B. carriers with a coincident sore throat probably caused by some other organism."

This is borne out by the fact that these patients usually have a very high antitoxic titre. The ordinary immune has about 1/20 unit of antitoxin, whereas the carrier of virulent bacilli usually has as much as 2 to 3 units per c.cm., and this may be of diagnostic value.

Routine Measures for Prevention of Diphtheria

The following remarks apply to *institutional* cases.

(*a*) Of the greatest importance is the adoption of routine swabbing of admissions. There is no doubt that by detecting the virulent carrier on admission the incidence of diphtheria in institutions has become enormously reduced. All patients with doubtful swab reports should be isolated until a virulence test has been done.

(*b*) All sore throats in hospital should be swabbed as well as *all* nasal discharges, particularly if these be blood-stained. Swabs from the anterior nares are apt to be fallacious and should, if possible, be accompanied by a post-nasal swab for confirmation.

(*c*) As soon as a positive swab is obtained all who have been in contact with the patient should be swabbed (throat and nose) and Schick-tested. All contact carriers can thus be immediately isolated before they cause any spread. The Schick-positives among those tested receive a protective inoculation of 1,000 to 2,000 units of concentrated diphtheria antitoxin, which gives them within one hour a passive immunity lasting about twenty-one days. Under this protection they will not develop clinical diphtheria, but they may, like any other Schick-immune, become the carriers of virulent bacilli. It should be borne in mind that K.L.B. isolated from a Schick-positive reactor, cannot be virulent unless the patient is incubating diphtheria. Harries[6] has pointed out that if a patient is Schick-positive and becomes a carrier he either develops diphtheria or rapidly becomes Schick-negative; the fate hangs in the balance for a few days (this is explained on the ground of secondary stimulus, see above).

(*d*) All permanent staff should be immunized on admission. This reduces the incidence among them to nil (except for carriers) and thus reduces the chances of infection for the patients. It would perhaps be advisable

also to swab the staff at regular intervals, particularly after an outbreak of diphtheria.

In all institutions where a long stay is contemplated the children as well as the staff should be actively immunized. In hospital this is not possible, but we can still admit new patients to an infected ward by Schick-testing and, if necessary, giving a passive immunity.

No immunization measure alone is of value in an epidemic; the only certain method is carrier control, both of convalescent and of contact carriers.

In *private and public health* work we cannot urge too strongly that as many children as possible, after the age of 1 year, should be Schick-tested and actively immunized until they are immune, preferably using T.A.M. or T.A.F.

Scarlet Fever

A specific haemolytic streptococcus is now identified as the causal agent of scarlet fever. It cannot be isolated from the blood in the early stages of the fever (except in fulminating cases), because the symptoms are those of a toxaemia, and it is not till later, when the septic complications occur, that the organisms can be at all readily obtained from lesions. The toxins of the streptococcus when injected in a dose of 0.1 c.cm. *intramuscularly* will produce a typical scarlet fever rash in about 7 per cent. of children; whereas if a dose of 1 or 2 c.cm. is used, all children injected will develop the rash. A similar rash can be obtained with a few other strains of haemolytic streptococci, but much larger doses are required.

The Dick Test

In the Dick test 0.2 c.cm. of a 1/1,000 dilution of the specific toxin is injected intradermally into the skin of the forearm, and a similar amount of toxin, heated to 100° C. for half an hour, is used as a control. A positive reaction is indicated by an erythematous area in the test arm, which appears within twelve hours, reaches its maximum in twenty-four hours, and then rapidly disappears. Pseudo-reactions do not occur in children, and are much rarer in adults than the pseudo-Schick reactions. Care must be taken not to inject too deeply, as the toxin will be readily absorbed and may give a false negative. This Dick test is a toxin-antitoxin reaction in the skin; the injected toxin being neutralized if there is sufficient circulating antitoxin.

It is said that children up to 6 months inherit an immunity from the mothers, but this is now challenged because their blood does not always cause blanching of a scarlet fever rash, and it has been suggested[8] that many of them do not react because of the general non-reactivity of the infantile tissues to streptococci. They lose this passive immunity or non-reactivity at about 6 months, and thereafter the majority are Dick-positive, slowly becoming negative in adult life. This alteration in the reaction, as in diphtheria, is probably due to repeated subinfections with the haemolytic streptococcus which is kept among us by carriers, both contact and convalescent. Treatment of scarlet fever carriers has not yet reached the stage attained in diphtheria, but in any institution with recurrent epidemics of scarlet fever it is advisable to take routine throat swabs, and isolate any persons who have haemolytic streptococci in their throats. It has also been suggested[9] that the complement fixation test is a useful means of isolating carriers, as they react positively, as do also 98 per cent. of scarlet fever cases from the second to the fifth weeks.

In *early cases* of scarlet fever only about 40 per cent. of patients are Dick-positive. This curious state of affairs is explained as follows:

(*a*) The skin has a diminished reactivity to all toxins in the early stages of an acute infectious disease. Both in scarlet fever and measles there is a lessened reactivity to tuberculin, streptococcus toxins, etc.

(*b*) The rash having already appeared as the result of the toxaemia, the skin is not so sensitive to further doses of toxin.

(*c*) It will be recalled that in the Schick test of a carrier it was emphasized that the reaction of a Schick-positive could be readily converted by a few bacilli in the throat acting as a secondary stimulus. In like manner the infection, if only for twenty-four hours, with the streptococcus may readily turn the Dick reaction negative. It can readily be seen that although it is advocated in diagnosis of an early scarlet fever rash, the Dick test is in itself insufficient evidence either way.

In convalescents 10 to 15 per cent. remain Dick-positive. There are various factors concerned in this persistence of the positive reaction.

1. Toyada[10] has split up the streptococcus toxin into exotoxin (heat-labile) and endotoxin (heat-stable). Of this 15 per cent., he found that 13 per cent. reacted *only* to the endotoxin factor and their bloods gave a good blanching reaction (Schultz-Charlton) when injected into a scarlet fever rash. They are immune. The other 2 per cent. gave reactions to both endotoxin and exotoxin and they gave weak blanching reactions. These are only partially immune, but a secondary stimulus would rapidly convert them into negative reactors. He holds that the endotoxic reaction merely indicates previous experience with the streptococcus and a partial immunity. He, therefore, advocates using only the heat-labile exotoxin both in the Dick test and in immunization.

2. Convalescents from scarlet fever who have been treated early in the disease with concentrated antitoxin show a much higher rate of Dick-positives (30 to 40 per cent.) than do other convalescents.[11] This would apparently indicate that the disease is fought "passively" and that the patient has no opportunity to produce his own active immunity which would be permanent.

3. Of the four serological groups of scarlet fever streptococci, it has been demonstrated[12] that many more patients remain Dick-positive after infection with Group 4 than with any other group, and least of all with Group 2. This suggests that Group 2 of the *Streptococcus scarlatinae* is most highly toxigenic and Group 4 least so. Finally, in cases of relapse it has occasionally been observed[13] that the infecting strain in the relapse is different from that in the primary attack. This would indicate that if a patient remains Dick-positive after an attack of scarlet fever with Group 4, he may become infected from another patient in the ward with a different serological strain.

Immunization in Scarlet Fever

Passive Immunity.—In an epidemic of scarlet fever, active immunization is obviously of no avail. We now have available a purified concentrated antitoxin serum which can be used both therapeutically (in severe toxaemic cases) and prophylactically. A small dose, 5 c.cm. intramuscularly, will turn a Dick-positive reactor negative within twenty-four hours, and this passive immunity will last two to three weeks. In hospital and institutional practice this has been a great boon. When a case of scarlet fever is reported in a ward all the inmates should be Dick-tested immediately. The results are read next day and serum is given to all positive and doubtful reactors at once, that is, twenty-four hours after the first rash appeared. The enormous success attendant upon the adoption of this routine can be attributed to the rapidity of the diagnostic reaction, as the whole procedure falls well within the incubation period for scarlet fever.

Active Immunity.—Small doses of toxin are injected at weekly intervals until at least 20,000 skin test doses have been administered. Our practice has been to inject 0.1 c.cm. scarlet fever prophylactic A (Burroughs Wellcome and Co.) intramuscularly. If there is no reaction within

three days the following doses are injected at weekly intervals: 0.4 c.cm.A, 1 c.cm.A, 0.25 c.cm.C, 0.5 c.cm.C, 1.0 c.cm.C, the total being equivalent to 38,500 skin test doses (prophylactic A contains 2,500 skin test doses per c.cm. and prophylactic C 20,000). Reactions, in the form of sore arm and malaise, occur but rarely and are not severe. Occasionally, however, a scarlatiniform reaction occurs. This takes the form of a toxaemia, the patient developing a scarlet fever rash, sore throat, and rise of temperature for twenty-four to forty-eight hours. All this rapidly subsides and none of the complications of scarlet fever ever occur because these are septicaemic and the reaction here is only toxaemic. The patient has now developed a high degree of active immunity and does not need further injections. The reaction is uncommon in adults (2 in 270 nurses immunized) but is said to occur in about 7 per cent. of children.[11] Immunity after the normal course of injections is usually complete within one month after the last injection, and is of many years' duration. If there are any signs of the Dick test again becoming positive another injection is usually all that is necessary.

Institutional Practice.—All staff should be Dick-tested and, if positive, actively immunized on entry. Similar measures should be adopted in public schools and other institutions where the children are resident for long periods. In an epidemic, the whole population should be Dick-tested and serum given immediately. By this means no second case of scarlet fever has occurred in our hospital for three and a half years. The isolation of *carriers* of haemolytic streptococci is a measure which we would urge in cases of repeated epidemics, as they will readily infect the patients as soon as the effects of the prophylactic serum have worn off, in about three weeks. Our wards are now not closed for scarlet fever, as all new admissions for ten days after a notified case are Dick-tested and passively immunized.

We wish here to draw special attention to a measure we have adopted for several years. Streptococcal infections with a rash and sore throat, etc., are fairly common after operations on the throat and nasopharynx. Surgeons are apt to disregard these and not look upon them as true scarlet fever. We have often seen two or three other children in a ward develop typical scarlet fever three days after such a case, and we therefore treat the rest of the ward prophylactically exactly as for a scarlet fever whenever such an infection occurs. Several of the surgeons at Great Ormond Street now have all patients for these operations Dick-tested *beforehand* and serum given where necessary, and have by these means eliminated such scarlatiniform reactions for several years. We would advocate this as a routine measure for all children's wards.

Private and Public Health Practice.—When confronted with contacts of scarlet fever in private practice each case must be treated on its own merits. Obviously if a child is in poor health we should not withhold our prophylaxis, but it is not an ideal state of affairs to have to give a child a dose of horse serum each time it is exposed to scarlet fever. It would be wiser when possible to provide the passive immunity once, and then commence as soon as is practicable a course of injections for active immunization. This would do away with the necessity for repeated serum injections with their attendant risks. In public health work we would advocate that all children who are Schick-tested should at the same time be Dick-tested. Both reactions are read on the first day and the Schick again on the third day. Thereafter the two courses of active immunity can be given concurrently, the two solutions being mixed in the same syringe just before injection. By means of this active immunity the scarlet fever incidence in Dairen has been reduced from 43.3 per 1,000 in 1925, to 1 per 1,000 in 1930.

Measles Serum

With regard to the use of human convalescent serum in the prophylaxis of measles we have not much to add to the paper[13] upon the subject which we read in the Section of Medicine at the Annual Meeting of the Association in Winnipeg last year. Further experience of the method confirms our opinion of the value of the procedure.

Historical

Nicolle and Conseil[16] in 1916 succeeded in protecting children who had been exposed to measles infection by injecting them with convalescent serum. Since then many observers have published similar results, which all agree in establishing the fact that convalescent measles serum is of very great value in prophylaxis when injected in adequate amount shortly after exposure to infection. Debré and Ravina[17] in 1923 suggested the use of convalescent serum to produce a mild attack rather than complete protection, and this would appear to be the more desirable method in many cases, particularly in home as opposed to institutional cases, because the mild attack of measles induced would give the patient an active immunity which is permanent, whereas the immunity produced by a prophylactic dose is passive and lasts only from two to four weeks. Owing to the difficulty in procuring sufficient supplies of human serum for its use on a large scale, it is obvious that as soon as a causal organism for measles is definitely established and an appropriate animal serum prepared, the use of human serum will be suspended. The animal serums at present available are those of Tunnicliff, Degkwitz, and Ferry and Fisher, all of which are prepared from a "green" streptococcus, which is held, though not generally accepted, to be the causal agent of the disease. Gunn,[18] of the Metropolitan Asylums Board, in a comparative survey of these animal serums and human convalescent serum, found that Ferry and Fisher's serum failed to protect, Degkwitz's serum protected 40 per cent., Tunnicliff's serum protected 43 per cent., and human convalescent serum protected 95.7 per cent. of the individuals injected. These results are similar to those obtained by other workers, and show that, at present, human convalescent serum is by far the most reliable. A similar condition obtains in poliomyelitis and encephalitis lethargica, which are virus diseases, and reference may incidentally be made to the observation of Degkwitz[19] on the cultivability of the measles virus, but McCartney[20] states that the prophylactic use of Degkwitz's animal serum, presumably made from the virus cultures, has not furnished any evidence that measles-virus immune bodies are present.

Preparation of the Serum

Children are obviously not suitable donors of adequate quantities of blood, so that we have obtained all our supplies from adults, and we have been fortunate in securing the co-operation of Dr. Massingham, of the London Fever Hospital, where many adult cases of measles are treated. Only normal, uncomplicated cases of measles are utilized for this purpose, and the greatest care is taken to exclude the possibility of any other infection, particularly syphilis or tubercle. From seven to fourteen days after defervescence patients are bled aseptically to the extent of 300 to 400 c.cm. into sterile oxalate solution, this procedure yielding as much as 60 per cent. of serum, after precipitation of the oxalate with calcium chloride. Sterility tests and a Wassermann reaction are done on every serum, and if these are satisfactory, 0.5 per cent. phenol is added, and the serum is pooled with several other serums, to ensure as far as possible a uniform potency of the final product. Before it is stored or bottled for use, the serum is filtered through a Seitz bacterial filter, and a final sterility test done.

Effects of Administration

No ill effects have ever followed the use of a carefully prepared serum, and any untoward results can usually be traced to insufficient care in the preparation The method of preparation which we have outlined above practically eliminates any possibility of conveying a tuberculous infection with the serum, for Kraus has tested many measles convalescent serums made without the double precautions (phenolizing and filtering) which we adopt and has never produced tuberculosis in the inoculated guinea pigs As the serum is of human origin, anaphylaxis or serum reactions do not occur, and it is unlikely that an attack of asthma or other allergic manifestation will be produced by the serum injections Different results can be obtained from the use of the serum, depending on the stage of incubation at which the injection is given

Injected before the fifth or sixth day of incubation, the serum affords complete protection—a passive immunity which lasts from two to four weeks This Copeman [1] calls "sero prevention" Injected on the sixth to the ninth day of incubation, the serum protects only partially, and a very mild attack of measles usually ensues ("sero-attenuation") Injected after the ninth day no benefit is to be hoped for from the serum whereas injection on the tenth day produces Debre's phenomenon—a local blanching at the site of the injection

The attenuated attack gives rise to a permanent active immunity, which is our aim in private practice where the individual himself has alone to be considered, whereas in institutional work it is complete protection which is aimed at Of course, where a very sick child has been exposed to measles, whether at home or in an institution, it must be protected at all costs, and one would inject the serum as soon as possible, and give a slightly larger dose than the normal for a child of that age The attenuated attack is usually a very mild affair a slight bout of fever (100° F) for a day or two at about the fourteenth day of incubation, others may be apyrexial, with a few measles spots on the trunk or face, others, again, may have a typical attack of measles with coryza and bronchitis, which has all subsided in twenty four to forty eight hours We have never seen Koplik's spots in any of these cases arising after the injection of convalescent serum Sometimes after a long incubation period—even as much as twenty six days in some cases—a mild attack of measles may occur which, from a hospital administration point of view, is rather disturbing, as it holds a ward in quarantine for nearly four weeks If, however, serum is given to all the new admissions, the quarantine period need not interfere with the normal working of the ward

Dosage

In order to ensure the production of complete protection, we have recently increased the doses of serum injected to 5 and 7 c.cm intramuscularly for children under 3 years and over 3 respectively Whole blood may be used instead of serum, in which case the blood of a convalescent is injected intramuscularly into the recipient, the amount injected being double the serum dose It has also been suggested that the whole blood or the serum of any healthy adult who has had measles may be used, and this scheme has recently been tried in Birmingham, where 146 children have been treated in this way The results are reported as very satisfactory, 57 children having had attenuated attacks (the result aimed at) and 85 children being fully protected Serum has been tried in the treatment of severe measles, but without success, as the antibody content is not sufficiently high, and enormous doses would be required to produce any effect For the same reason the serum is unable to blanch the rash, although it is sufficiently potent to prevent the appearance of the rash in an area if injected shortly before the general rash appears (Debre's phenomenon) *

Results

Debre Gunn, and many others, have reported complete protection in from 80 to 96 per cent of the cases injected Our own series now amounts to 625 cases, in which the advocated dose of serum was injected within the first five days of exposure to infection, and a further 46 cases in which either too little serum was injected or an adequate dose was injected between the sixth and ninth days of incubation Of this total of 671 cases, 518 were injected by us at the Children's Hospital following ward infections, and 153 cases from practitioners in various parts of the country, following home or hospital infections

Analysis of Cases Injected

It is impossible to say how many children exposed to infection would develop measles but Gunn, working at a fever hospital, and with facilities for studying cross infections, had ample opportunities for controls His series included uninoculated wards, and wards inoculated with

ANALYSIS OF CASES INJECTED WITH CONVALESCENT MEASLES SERUM

1. Cases at the Hospital for Sick Children, Great Ormond Street
2. Cases at other hospitals and of private practitioners

	Injection Made Before 5th Day	Protection	Failures	Injection 6th–9th Day	Protection	Attacks
1	514	507	7 (Attacks mild)	4	0	4 (3 mild, 1 severe)
2	111 / 35	106 / 0	5* / 3†	33	25	8‡

Total 625 appropriately injected with 611 cases = 98·1 per cent protection

* In these cases the rash appeared 8 to 21 days after the serum was given and the attacks were all mild or very mild

† These cases were all mild and the rash appeared in 8 to 10 days after the serum was given In several of these cases erroneous information rather than too little serum was given at

‡ In these three cases too little serum was injected

various animal serums and with convalescent serum His 95·7 per cent, together with our figure of 98·1 per cent, protection affords striking and sufficient proof that, until an efficient animal serum is prepared, convalescent measles serum is the best weapon we have for preventing measles, and it should be more widely used than it is at present

UNDULANT FEVER CONVEYED BY MILK*

BY

SIR WELDON DALRYMPLE-CHAMPNEYS, Bt., M.D.

I have been asked to open this discussion on milk-borne diseases with a consideration of the part played by milk in the spread of undulant fever. Now I am not going to pretend that in this country undulant fever is either the commonest or the most serious disease conveyed by milk, but its significance in this respect is certainly far from negligible even here, and in some foreign countries it has loomed very large in recent years. One indication of this is that in the time at my disposal it will be impossible for me to deal with more than a small fraction of the evidence which has accumulated of the dangers arising from milk containing organisms of the Brucella group.

The first indication of this danger was, as you know, given by Horrocks,[1] who, following up Zammit's discovery[2] of the natural infection of Maltese goats with the *Brucella melitensis*, found this organism in large numbers in the milk of one of these animals. Further investigations by the British Commission on Mediterranean Fever showed that the blood serum of about 40% of the goats in Malta agglutinated the causative organism and that numbers of apparently healthy goats in every herd were excreting *M. melitensis* in their milk and urine. The outcome of these discoveries was of course the famous order to the naval and military forces at Malta forbidding the consumption of unboiled goat's milk, one of the most dramatically successful prophylactic measures ever taken in the history of preventive medicine.

This step, however, did not end the career of caprine crime, and goats are still spreading this serious disease not only in Malta but in all Mediterranean countries, in the southern portion of the United States, and elsewhere, the chief but not the only vehicle of this infection being their milk. That the same role was being played by sheep was unsuspected until Dubois[3] reported in 1910 four groups of cases of *melitensis* infection among sheep on different farms in the department of the Gard (France), with three of which human cases of the disease were associated. Subsequent investigations have clearly established that sheep, so far from being exceptional vectors of the disease, are probably the most important agents of its spread in France. The conditions in that country are, however, exceptional, and in Denmark, Sweden, Germany, Switzerland, Holland, South Africa, Rhodesia, the United States and other countries, among which is our own, the chief agent of spread is not the goat or the sheep but the cow. The story of how the cow came to be suspected and was eventually convicted, starting with Alice Evans's[4] discovery of the very close relationship between the *Micrococcus melitensis* of Bruce and the *Bacillus abortus* of Bang, I have told elsewhere,[5] and there is no time for it here. I would like, however, to draw attention to the fact that the view held at first that bovine infection is nearly always conveyed by infected milk has had to be modified in recent years in consequence of the important part which direct contact with infected cattle has now been shown to play in the transmission of infection to man.

I am only concerned now with undulant fever conveyed by milk, and there is good reason to believe that the consumption of cow's milk containing the *Brucella abortus*, the cause of contagious abortion in cattle, has been and still is the commonest cause of undulant fever in Great Britain. Before considering the situation in this country it is essential that I should give a brief account of the evidence in regard to milk recently obtained in countries where many more cases of the disease have been reported and studied. First of all I must recapitulate a few of the facts with regard to the animal disease known as contagious abortion of cattle and due to infection with the *Brucella abortus*. Bovine animals of both sexes and at all ages are liable to this infection, but the disease is most severe in young heifers. Abortion usually occurs between the fifth and seventh month of pregnancy, but some cows abort about the first or second month. Not only is the disease often unsuspected but even abortion often passes unnoticed. This is largely because, as the British Commission found with the Maltese goats, the animal's general health is usually quite unaffected.

Pathological changes are generally confined to the uterus though the organisms may be widely scattered and the udder usually becomes infected, so that apparently healthy animals may excrete large numbers of Brucellae in their milk, the organisms again making their way to the uterus when pregnancy occurs. An important point to note is that something like 80% of aborting cows only abort once, though they may continue to harbour and excrete the organism for a long time after aborting. (Schroeder and Cotton observed a cow which continued to excrete the organism in her milk for seven years.)

Moreover a large proportion (perhaps 50%) of infected cows never abort, and the *Brucella abortus* has often been found in the milk of cows which have never aborted. About 30% of infected cows excrete the organism in their milk sooner or later.[9] In most countries where cattle raising is of any importance contagious abortion is rife and a serious proportion of the milk supply is infected with the causative organism. In America, for instance, Schroeder and Cotton[6] found the abortion organism in over 10% of 77 samples of market milk which they examined, and in the milk distributed by 6 out of 31 dairies (over 19%). In Pomerania (Germany) Pröscholdt' examined 3,000 samples of whole milk by guinea-pig inoculation (the most reliable method) and found that 27.5% of these samples contained the *Br. abortus*. Even higher proportions have been found by other observers in different countries. Some infected cows, apparently never excrete the organism in their milk, but such excretion is often intermittent.[8]

In Great Britain, unfortunately, very little work has been done to ascertain the extent to which the milk supply is contaminated with the organism of contagious abortion, nor are there any statistics available to show what proportion of our milch cows are infected. Rabagliati[9] believes that at *least* 50% of our herds contain infected cows, and other experienced veterinarians have given similar estimates.

Wilson and Nutt's[10] investigation of the milk supply of Manchester, in which they examined 488 samples and found that 5.7% of single milks and 8.8% of mixed milks contained the *Br. abortus*, is still almost the only observation on record indicating the extent to which the milk supply of this country may be infected; but Cruickshank and Barbour[7] recently found that 4 cows out of a herd of 37 (i.e. 10.8%) supplying a Scottish institution with milk were infected.

Further systematic examinations of milk supplies in Great Britain, if possible by guinea-pig inoculation, are badly needed, but if, as can hardly be doubted, they reveal that a considerable proportion of our unpasteurized milks contain the *Br. abortus*, what is the explanation of the small number of human cases of undulant fever so far discovered? At the time of writing only 34 *definite* cases of endemic origin in England and Wales and 5 in Scotland are known to me, though I have in addition records of a number of unproved cases in some of which the probability of this infection having occurred appears to me to be very strong. In Rhodesia, on the other hand, where conditions

* Read in opening a discussion on Milk-Borne Diseases Other Than Tuberculosis in the section of Pathology and Biochemistry at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

abortion is not so rife as in this island, Bevan[10] reports that more than 200 human cases (in a European population of only 45,000) have been diagnosed serologically within the last ten years. In the United States 1,305 cases were reported during 1929.[11] In Denmark between 300 and 400 cases have been diagnosed every year since Kristensen started his systematic investigations.

I have no time now to discuss the possible explanations of this remarkable contrast between the small number of human cases reported in Great Britain and the wide distribution of bovine contagious abortion, but I venture to predict that further investigations will show that undulant fever is much commoner with us than would appear at present, a large proportion of the infections being so slight that the patients never call in a doctor and perhaps never regard themselves as definitely ill. In that case, you may say, the disease is hardly worth bothering about. Let us beware, however! Undulant fever is a disease full of unexpected tricks, with an epidemiology many parts of which are still shrouded in mystery. Take for instance the unexpected discovery in America of infection of swine with a Brucella highly virulent to man, or the recent finding in the Jura Alps of human cases of bovine origin when infection from this source was supposed to be practically non-existent in France. The English strains of Brucella are, moreover, not all benign, or at any rate some of the population have a susceptibility to them which is far from negligible. It is no joke when you have taken care of your health and always drunk the most expensive graded milk to be incapacitated for five or six months with a disease which, if not dangerous, is at any rate most miserable and depressing.

To return to milk, it should be noted that undulant fever, unlike some of the milk-borne diseases of which we shall hear presently, does not occur in epidemic outbursts among the consumers of an infected supply. It is true that considerable groups of cases have occurred in connexion with a single supply, especially in institutions producing their own milk,[8 12 13 14] but individual susceptibility seems to play such an important part that usually only a small proportion of the consumers are affected. Even when a group of cases appears in one place it is often impossible to trace them to a single milk supply, or to any other common origin, as you will see was the case in the group occurring in this town, of which Dr. Shera is going to tell you presently.

It has only been possible in the short time at my disposal to give a fleeting glimpse of the problem presented by the spread of undulant fever by means of milk; but I hope that I have succeeded in showing that it is an intricate problem and an important one, that it must be taken seriously into account in the consideration of any measures designed to protect the milk consumer from disease, and finally that research in this direction is urgently needed and provides a most fascinating and profitable field for the bacteriologist, the veterinarian and the epidemiologist.

FOUR CASES OF UNDULANT FEVER*

BY

A. GEOFFREY SHERA, M.A., M.D.Camb.,

CONSULTING PATHOLOGIST TO THE EASTBOURNE HOSPITALS, AND TO THE EAST SUSSEX COUNTY COUNCIL

The four† cases about to be described occurred here in Eastbourne at the latter end of 1930. The first was a youth, aged 16, who was admitted to the Princess Alice Hospital on September 15th. The second was a member of the visiting surgical staff of this hospital, but not actually in attendance on the first case. The third was a boy at one of the schools here, and the fourth was a former house-surgeon to the hospital above mentioned, who was staying in Eastbourne on holiday. Whether there was any direct infection between the various cases is a point for speculation. The house-surgeon was engaged to be married to the sister in charge of the ward in which the first case occurred, and the practitioner attended the school in which the third case occurred. The last two patients became ill at the same time, so that a simultaneous origin from a common milk supply is much more probable than a direct infection. The public health authorities were, unfortunately, unable to trace the source of infection via milk, but this was almost certainly the mode of origin. It will be as well to sketch the clinical histories and pathological findings first, and then to compare the cases afterwards.

Case 1

G. M., aged 16, was admitted to the Princess Alice Hospital on September 15th, 1930, and was discharged cured on December 10th. There was a history that in August, 1930, he camped on a farm near Pevensey, and drank a good deal of milk at that time. About a month before admission he complained of malaise, tiredness, anorexia, constipation, shivering, headache, and backache. A week later he gave up work and went to bed. For three weeks he had been running a temperature between 100° and 104° F., and was attended by Dr. Percy Vosper of Hailsham. There had been no nausea, no vomiting, and no diarrhoea.

The blood count on October 9th showed the following features: red cells, 5,360,000 per c.mm.; haemoglobin, 63 per cent.; colour index, 0.58; leucocytes, 5,600 per c.mm.—of these, 60 per cent. (3,360) were neutrophils, 30 per cent. (1,680) were lymphocytes, 10 per cent. (560) were monocytes—and 24 per cent. were immature neutrophil cells. Eosinopenia was present, also some microcytosis. The leucocyte count on October 16th was 4,400 cells per c.mm. On October 24th the blood count was as follows: red cells, 5,980,000 per c.mm.; haemoglobin, 76 per cent.; colour-index, 1.06; leucocytes, 4,600 per c.mm.—of these, 55 per cent. (2,530) were neutrophils, with 28 per cent. immature forms, and 45 per cent. (2,070) lymphocytes. An enteric group infection was suggested.

On October 27th, the diagnosis still being obscure, and headache being a prominent symptom, a detailed examination of the spinal fluid was made, including a cell count estimation of chlorides and total protein, Pándy and Nonne-Apelt tests, a gold-sol curve, and a bacteriological examination, with negative results throughout. The blood was also examined for the Wassermann and tubercle complement-fixation tests, and on October 15th and 20th the Widal reactions against *B. typhosus*, *B. paratyphosus* A, B, C, and the Salmonellas were done, with negative results. A throat swab was taken, as there was sore throat (see Case 4), but this was negative to Klebs-Loeffler bacillus. On October 27th the blood was agglutinated against *Brucella abortus*, and was found to be strongly positive up to 1 in 5,000 (2,500 units). On December 9th, the day before the patient was discharged from hospital, the blood was positive up to 1 in 500 (250 units). Blood cultures were negative on two occasions. Partial anaerobiosis was tried by means of pyrogallic acid and soda desiccating jar.

* Read to the Section of Pathology at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

† After going to press a fifth case was subsequently traced, which had left the town.

This was deemed to be equally effective as the introduction of 10 per cent. carbon dioxide, as recommended by Wilson. Possibly it was not.

The patient felt remarkably well while in hospital. The pulse rate ranged between 88 and 120, and the respirations remained constant at 20. The bowels, although occasionally constipated, were usually opened once or twice daily. The urine was normal, and sterile on culture. Examination of the chart shows four typical undulations—the first lasting two weeks, with an interval of four days' apyrexia; the second, a smaller rise lasting two weeks, with two days' apyrexia; and a third brisk one, lasting one week, succeeded by a permanent fall.

Case 2

The history in this case was that, about October 5th, the patient, a male aged 45, had a temperature of 102° for one day, from which he recovered. A week later the temperature was 100.6°, and he went to bed with the following symptoms: extreme tiredness, marked anorexia, mental depression, drenching sour-smelling sweats, headache, insomnia, a dirty foul tongue, and constipation. He felt ill when the temperature was up, but felt quite well when it was down. He was at no time prostrated. I saw him after he had been ill for some three weeks, and was asked to investigate this pyrexia of unknown origin.

On November 1st a leucocyte and differential count showed the total leucocytes to be 4,800 per c.mm., with 35 per cent. neutrophils, of which no less than 20 per cent. were immature. The lymphocytes were 59 per cent. and monocytes 6 per cent. Eosinopenia was present. The significance of immature forms is that they indicate an acute infection when raised considerably above the normal 4 per cent. The Widal reaction showed *B. typhosus* to be positive 1 in 25 (R.T.* 3.75), *B. paratyphosus* A positive 1 in 125 (R.T. 31.25), and *B. paratyphosus* B 1 in 25 (R.T. 2.5). Although the patient had been inoculated during the war, I suspected *B. paratyphosus* A infection. The blood was cultured, also the faeces and urine, with negative results for the group. The Widal reaction was repeated on November 8th, with the same result. There being no rise of titre, this was against *B. paratyphosus* infection. Agglutination to *Br. abortus* was tried with two separate strains, and I got a positive result up to 1 in 250, which was very kindly confirmed by Dr. A. D. Gardner of the Standards Laboratory, Oxford University. Undulant fever was then diagnosed; the clinical syndrome was typical.

A leucocyte and differential count on November 12th showed 8,400 leucocytes, with 42 per cent. neutrophils (2 per cent. of which were embryonic forms) and 54 per cent. lymphocytes. The agglutination reaction on this date had fallen to 1 in 125, and the leucocyte count likewise indicated less active infection in the rise in count and drop in embryonic neutrophils. On November 17th the leucocytes had dropped to 4,400, with 55 per cent. lymphocytes. On December 2nd the blood serum agglutinated *Br. abortus* up to 1 in 50. On December 22nd a complete blood count was done in order to see whether there was any anaemia. The result was as follows: red cells, 4,750,000 per c.mm.; haemoglobin, 74 per cent.; colour index, 0.78. The cells were normal in every way except for a trace of undue transparency. Platelets were numerous. The white count was as follows: leucocytes, 3,200 per c.mm.; neutrophils, 40 per cent. (embryonic forms 19 per cent.); basophils, 1 per cent.; eosinophils, 1 per cent.; lymphocytes, 54 per cent.; monocytes, 4 per cent. The count showed slight secondary anaemia, with leucopenia and lymphocytosis and a good many immature neutrophil cells. On December 22nd the serum agglutinated *Br. abortus* up to 1 in 50.

Two injections of nucleinic acid were given, one on November 10th, which coincided with a rise to 101°, and the second on November 15th, which caused a rigor. On November 30th, December 1st, 2nd, 3rd, 4th, and 5th, "edwend" was given in increasing doses, ranging from 1 to 5 c.cm.; thereafter all went well. The patient became convalescent, and went to the South of France; he has resumed work without any further recurrence. One feature which is common to these cases is the drop in agglutination titre which accompanies the subsidence of the complaint.

Case 3

In this patient, a boy aged 10, the illness began acutely on November 8th, simulating influenza, according to the medical attendant. It was treated as such with salicylates for the first ten days. It was diagnosed as undulant fever on November 23rd. The symptoms observed were profuse sweating, obstinate constipation, headache, anorexia, a very dirty tongue, and some loss of weight during the first month.

The pathological tests were as follows: On November 23rd, leucocytes were 4,200 per c.mm., with neutrophils 38 per cent.; lymphocytes, 52 per cent.; monocytes, 10 per cent.; embryonic neutrophils, 10 per cent. (normal 4 per cent.);

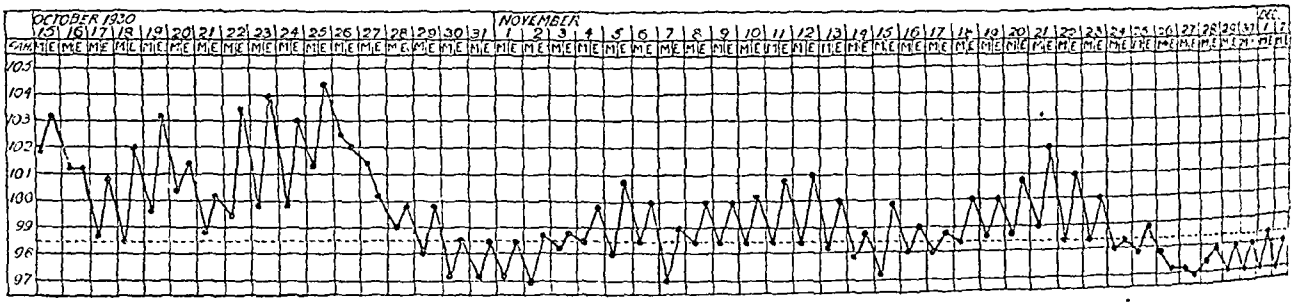

Chart of Case 1.

there were no eosinophils. Agglutination reactions were negative to *B. typhosus*, *B. paratyphosus* A, and C, and positive to *Br. abortus* up to 1 in 2,500.

A stock vaccine of *Br. abortus* was recommended and used with an initial dose of 12.5 millions and a second dose of double that amount on December 10th and 16th, and 37.5 millions on the 23rd. But the result was unfavourable inasmuch as the patient and his temperature seemed upset thereby, and so the vaccine was discontinued. However, he became apyrexial shortly after—with the exception of a single day—and made a slow but successful convalescence.

In this case there was no determined source of infection. The milk supply was suspect, and steps were taken to find out if there was any contagious abortion on the farm whence the supply came, but no positive data were obtained.

The duration of pyrexia was seven weeks, possibly eight.

Case 4

In this case, a male aged 25, the onset was insidious. Prior to November 17th there was increasing lassitude and slight sweating on exertion for a few days. On November 17th he noted loss of appetite and general malaise, with temperature and pulse 100. The temperature was reduced by aspirin. He went out after four days, and relapsed the same evening—temperature was 100° in the evening and 99° in the morning. He was admitted to hospital on November 27th—when the diagnosis was made—with enlarged cervical and inguinal glands as a marked feature. At first leukaemia was suspected, until the blood examination revealed positive agglutination to *Br. abortus*. The symptoms became more typical. There were sweats, constipation, insomnia, and some pains in the small of the back in the first week. Generally speaking, he felt well in health. The appetite after the first three weeks was good. He had an attack of follicular tonsillitis from November 30th to December 5th. The glands began to go down by the beginning of the fourth week. Salol was used during the

* R.T. = reduced titre (standard units of agglutinin).

as an intestinal antiseptic Nucleinic acid was also used in 1 c.cm. doses subcutaneously on four occasions early on

On November 25th leucocytes were 6 600 per c.mm. with neutrophils 22 per cent., eosinophils absent, lymphocytes 74 per cent., monocytes 4 per cent. On November 26th the blood agglutination was positive for *Br. abortus* up to 1 in 250 (trace at 1 in 500)—that is, 125 standard units. On December 9th the red cells were 4 950 000 per c.mm. with an average diameter of 7.17 μ. Haemoglobin was 82 per cent., colour index was 0.82; platelets were unreduced. Leucocytes were 10 000 per c.mm. with neutrophils 9 per cent., lymphocytes 90 per cent., monocytes 1 per cent., embryonic neutrophils 3 per cent. Agglutination was positive up to 1 in 125 for *Br. abortus*. Blood count on January 3rd 1931 was as follows: red cells 6 050 000 per c.mm. (average diameter 7.48 μ.), haemoglobin, 82 per cent., colour index 0.68; leucocytes 7 000 per c.mm.—neutrophils 64 per cent., basophils 1 per cent., eosinophils 1 per cent., lymphocytes 29 per cent., monocytes 4 per cent., Turck cells 1 per cent., embryonic neutrophils 5 per cent. On that date agglutination was 1 in 125 (and also on several subsequent occasions). A throat swab examined on December 1st was negative for Klebs-Loeffler bacillus.

The titre of agglutination was never high but was rather sustained. There was an initial drop in red cells which soon was followed by a rise. Iron was given by the mouth. The initial relative lymphocytosis was very marked but subsided when the glands went down. The adenitis was not met with in the other cases, but may occur in this disease. The patient made a good recovery.

Comment

The source of infection was untraced, despite the inquiries undertaken by the public health authorities. The only thing at all significant is the fact that there was a severe outbreak of contagious abortion within a few miles of the farm where the first patient lived. The disease was active in the neighbourhood, but no direct connexion was found. It is more likely that infection occurred during the August camping incident. The second patient gave a history of eating some rancid butter on a farm quite close to another infected farm. The third patient drank milk from a most reputable local firm which had no history of recent contagious abortion. Case 4 was possibly an indirect contact with Case 1.

Blood cultures were tried in Cases 1, 2, and 4, but with negative results. Glucose broth was used aerobically and partially anaerobically, and subcultures were made daily on human citrated blood veal digest agar.

The dates of commencement were as follows: Case 1, September 15th, 1930; Case 2, October 5th; Case 3, November 8th; and Case 4, November 13th. The duration was as follows in these four cases: Case 1, sixteen weeks; Cases 2 and 3, nine weeks each; Case 4, seven weeks.

All cases were fairly mild. Adenitis was marked in Case 4. Most showed leucopenia and lymphocytosis, the latter being specially well marked in Case 4. The maximum agglutinations were: 1 in 5,000 in Case 1, 1 in 2,500 in Case 3, with 1 in 250 (trace at 1 in 500) in Cases 2 and 4. These titres I think, run parallel with the severity of the cases. The drop in titres was as follows: in the first case, 1 in 5,000 to 1 in 500; in the second, 1 in 500 to 1 in 50; in the third, 1 in 2 500 to ?; and in the fourth, 1 in 500 to 1 in 125 (repeated twice). It would seem therefore, that a drop in titre is a good prognostic sign.

It might perhaps be worth pointing out that a sudden onset with a considerable rise of temperature, such as occurred in Case 3, is apparently no indication that the illness will be particularly severe or prolonged. The typical undulant chart of Case 1 is also interesting as this type of chart, which is so common in *melitensis* infections, is very uncommon in *abortus* infections. Case 4 at first was very obscure, resembling acute leukaemia of the aleukaemic type. Glandular fever was also suspected, but the picture became typical of undulant fever, and was confirmed by agglutination tests. I was not aware, until so informed by Sir Weldon Dalrymple-Champneys, who very kindly came and confirmed these diagnoses for us, that in these cases the organism can be cultured from the tonsillar swabs.

The primary object of this paper is to emphasize the importance of being on the look-out for undulant fever, I also hope to have indicated the chief pathological features calling for investigation.

Sir Weldon Dalrymple-Champneys has dealt with the epidemiology of the disease. It has probably been with us unrecognized for some time past but there should not now be any reason why it should be overlooked in the future.

We must acknowledge our debt to Sir Weldon Dalrymple-Champneys of the Ministry of Health for all the help he has afforded both clinically and in a literary sense. I also gratefully acknowledge the help of Dr. Deane, senior physician to the hospital, Mr. H. G. Estcourt, Dr. A. D. Gardner, and Mr. Patrick Laidlaw.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

APPARENT GONOCOCCAL CROSS-FIXATION

In a recent article by Dr. Orpwood Price on the gonococcal complement fixation test (*British Medical Journal*, April 4th) he refers to the *Micrococcus catarrhalis* as one of the causes of false positive reactions. A case which has recently come under my observation illustrates the cross-fixation with the *Micrococcus flavus* I.

The subject, a male child aged 18 months, was brought to the London County Council (Whitechapel) Clinic by his mother who wished to ascertain if there was any evidence of gonorrhoea about him, as his father had had venereal disease.

The father's history revealed a gonorrhoeal infection in India in 1926. For four months he had been attending St. Thomas's Hospital Clinic and was discharged cured four weeks before admission to the London County Council (Whitechapel) Clinic on April 10th 1931. He complained of twenty-one days' urethral discharge accompanied by marked dysuria following marital coitus twenty-four days previously. On examination the patient showed a slight watery urethral discharge in which no gonococcal or pus cells were detected by microscopy. The right lobe of the prostate showed slight enlargement generally but nodules, cragginess and tenderness were absent. A moderate number of pus and epithelial cells were found in the secretion obtained after prostatic massage, while the urine was clear and contained no threads. On palpation the testicles felt normal. The Wassermann and Kahn reactions and the gonorrhoeal fixation test were all negative.

The mother stated that she was six months pregnant and that for some months she had noticed a slight discharge which was unaccompanied by irritation or dysuria. She had had one child and had had no miscarriage, which as far as she knew she had no history of venereal disease. On recall there was a moderate degree of urethritis and a profuse purulent discharge from the cervical canal. Pregnancy was confirmed. The smears taken from the urethra and cervical canal showed a large number of pus cells and secondary organisms. Staphylococci and streptococci were grown from the urethral culture, that from the cervical canal showed streptoco-

cocci only. The gonococcal fixation test was negative, and also the Wassermann reaction.

The child on examination appeared healthy and well nourished. There was no history of illness, eye trouble, or nasal discharge. Urethritis and balanitis were absent, and the rectum appeared normal.

On the first visit routine blood tests were taken, and the results were reported as follows: Wassermann reaction negative, gonorrhoeal fixation test positive (+). On the second visit the blood tests were repeated, with the same result. As there was no clinical evidence to support these findings, further investigation was necessary. On the next visit cultures were taken (*a*) from the nose, (*b*) from the posterior fauces. Culture from the nose showed: pneumococci, staphylococci, streptococci, diphtheroids, and Gram-negative diplococci resembling *Micrococcus catarrhalis*. Culture from the posterior fauces showed: pneumococci, streptococci, and the above-mentioned Gram-negative diplococci. Subcultures were made and the sugar reactions tested. These proved that the organism was not the gonococcus, meningococcus, or *Micrococcus catarrhalis*, but *Micrococcus flavus* I.

In view of the fixation of the complement when employing a gonococcal antigen, it is probable that this is a case of cross-fixation. No parallel reactions could be performed to establish an end-point by using gonococcal and *flavus* antigens, with decreasing quantities of serum, as no antigen of *M. flavus* I was available.

The report illustrates that in translating the results of the gonococcal fixation test careful consideration must be made of the clinical and other pathological findings if error is to be avoided.

I have to thank Dr Anwyl Davies, director of the Whitechapel Clinic, for permission to publish this case, and Dr I N Orpwood Price for carrying out the pathological investigations

W. Neville Mascall, M R.C.S , L.R C.P.,
Chief Assistant, L C C. (Whitechapel) Clinic, E 1

" MIRROR TRANSPOSITION " OF VISCERA

This striking developmental anomaly is perhaps sufficiently rare to justify putting another case on record. The condition was found at a post-mortem examination on a man, aged 59, who had committed suicide by coal-gas poisoning. A state of " total heterotaxy " was seen.

Heart lay with apex projecting to the right
Aorta arched to the right, with innominate artery on the left
Right lung consisted of one lobe
Left lung consisted of three lobes, with a separate bronchus to its large upper lobe
Oesophagus crossed aorta from left to right
Stomach, which was considerably dilated, lay with its cardiac end on right and pylorus on left.
Duodenum passed from left to right
Caecum and appendix lay in left iliac fossa
Sigmoid colon was in right iliac fossa.
Spleen was in right hypochondrium
Main part of *liver* and the *gall bladder* were in left hypochondrium
Kidneys were joined together at lower poles to form a " horse shoe "

Thus there was practically complete transposition of viscera. Apart from the dilatation of the stomach no evidence of disease was seen. There was a history that he had had three attacks of pneumonia in the course of his life, and, latterly, had suffered from " indigestion " and wheezy breathing. Otherwise he appears to have had pretty normal health, and is stated to have been an exceptionally fine athlete in his youth. Curiously enough, he had some consciousness of his odd construction. He was wont to observe that he was " made different from other people." According to his wife, the beat of his heart on the right side had been noted [illegible] ago.

Rees Phillips, M D., D.P.H.

Reviews

DIABETES

The fifth edition of Dr. Orlando Petty's book on *Diabetes*[1] has been considerably enlarged, and remains a " handbook for the patient." Its introductory section on what diabetes is, on the different kinds of foodstuffs, on calories and scales and weighing, is entirely clear and adequate. The directions about insulin injections, over doses of insulin, and general hygiene are also good, and cannot be misunderstood by the average patient. It seems, however, a useless labour to recommend the insulin syringe to be boiled for five minutes daily as well as to be kept in surgical spirit. Dr. Petty arranges his food tables in the old-fashioned method (old-fashioned in this country) of percentage composition. The carbohydrate food values are also based on old analyses, and it will appear curious to many readers to see beets and radishes classed in the same group as containing 6 per cent. carbohydrate. The calculation of food values in the sample diets is surely carried to an impossible and laborious degree of accuracy when the figures are worked out to hundredths of a gram, as on page 116. Included in the book are some interesting tables of subjects which receive little attention in the treatment of diabetes in this country. For instance, a complete list of the vitamin content of food is given ; another of the salt (NaCl) content of foods, and another of their acid or base content. Whether these subjects are of much importance in the management of the average (or any) case of diabetes seems doubtful, and it must complicate the arrangement of diet for the diabetic, who usually has sufficient to think about in arranging his grams of carbohydrate, protein, and fat. Altogether we do not think that in respect of simplicity Dr. Petty's schemes compare favourably with those in common use in Britain.

Dr. Izod Bennett's book, *The Practical Treatment of Diabetes*,[2] is much more human. It is also shorter and yet covers more ground, and will appeal almost more to the practitioner than to the patient. The diagnosis of diabetes mellitus is first dealt with clearly, and benign glycosuria (renal) is differentiated from true diabetes, emphasis being laid on the importance of blood sugar tests. His statement, however, that carbohydrate food makes little or no difference to the excretion of sugar in renal glycosuria is hardly true, and the test described on page 12 would lead to a certain number of renal glycosurics being classed as diabetics. Dr. Bennett next proceeds to the practical details of treatment, and it is refreshing (and probably true) to hear him state that diabetes is " in theory an incurable disease," though admitting of improvement in tolerance under adequate treatment. His statement of practical procedure in treatment is very clear, and he insists on the use of insulin whenever an adequate diet does not *completely* control glycosuria or even hyperglycaemia. He advocates initial starvation and gradual building up of the final diet, a method which some will think laborious and slow in these days of insulin. When at any stage of building up the diet glycosuria appears, he controls that with insulin and then gradually increases the diet and the insulin to meet it, acting on the assumption that one added unit will burn one additional gramme of carbohydrate. This would seem likely to lead to hyperglycaemia, because it is generally agreed that an average of one unit of insulin usually metabolizes about 5 grm.

[1] *Diabetes*. By Orlando H. Petty, M.D., F.A.C.P. Fifth enlarged edition. Philadelphia: J. A. Davis Company. 1931. (Pp. 231. 2 dollars net.)

[2] *The Practical Treatment of Diabetes*. By J. Izod Bennett, M.D., F.R.C.P. London: Constable and Co., Ltd. 1931. (Pp. 107, 4 figures. 6s. net.)

of carbohydrate. He describes very helpfully the adjustment of diet which may be necessary when one, two, or three daily injections of insulin are necessary. The technique of insulin injections, the symptoms and treatment of hypoglycaemia and coma, and indeed all the essential points, are well dealt with. Probably the inclusion of a section on how to deal with ordinary illnesses complicating diabetes would be most welcome to the average practitioner, who finds this his most difficult problem. Short sections on diabetes in pregnancy and in children and the relation of this disease to life assurance are among the best in the book, and we could wish them longer. In the arrangements of diets Dr. Bennett uses Dr. Lawrence's 5-gram tables from *The Diabetic Life*, and these are reproduced in full. It is unfortunate that the food values in the graduated diets on pages 39-45 do not agree with these food tables, and contain discrepancies which must puzzle the patient. The statement also (p. 47) that the eighth-day diet contains nearly 2,000 calories, whereas it is nearer 1,500, should be corrected.

THE SURGERY OF CHILDHOOD

Although the imprint "third fully remodelled and enlarged edition" on the title-page of The Surgery of Childhood,[3] by Professor DRACHTER and Dr. J. R. GOSSMANN of Munich, tells us that it is by no means a new book, yet this is the first example of the work to come under our notice. In their preface the authors refer to the wealth of material to be found in German and foreign books, on which it is founded in part; but it rests still more on their own observations and experience of many years' work in the surgical section of the Munich University Paediatric Clinic. Naturally it shows in many respects a personal complexion. Only those methods of treatment are discussed of which the authors have had experience, and of which they have proved the value. Consequently those subjects which have most interested them receive the greatest attention. The kidney is discussed much more fully than in other works on the subject, and many anomalies and disorders of the child's urinary tract are given that consideration which is their due, but which they do not always receive, considering their direct diagnostic importance in troubles of the child's abdomen.

Orthopaedic surgery is not included in this work, but readers are referred to the separate volume on that subject by Professors Hans Spitzy of Vienna and Fritz Lange of Munich. Notwithstanding this large omission the volume is a goodly one. To show the scale of the work it is only necessary to mention that 50 pages and 80 figures are devoted to the consideration of hare-lip and cleft palate, and 140 pages and 90 figures to the urogenital tract. Yet there is a certain want of proportion, for, while phimosis is illustrated by 26 coloured figures, tuberculosis of the lymphatic glands is dismissed in 5 pages and 2 figures. It is apparent that the authors are in general more keenly interested in the surgical pathology of childhood, and in developmental and congenital defects, than in the practical surgery of infancy. Nevertheless, although so great a part of the book is devoted to pathology, there is room in these 1,031 pages for much surgical information. Professor Gossmann's large experience has furnished many unusual clinical pictures, which he offers for our instruction.

Osteomyelitis and injuries of the bones and joints are included in this volume, though tuberculosis of the bones and joints is scarcely alluded to. Presumably it is relegated to the volume on orthopaedic surgery. This specialization has its drawbacks, seeing that the differential diagnosis between streptococcal and tuberculous spondylitis is as much a matter for the paediatric as for the orthopaedic surgeon, and many common questions of treatment are involved. On visiting the surgical wards of a children's hospital in this country the visitor cannot fail to notice the share which is taken in treatment by plaster-of-Paris, but in this book its equivalent in German—"gips" or gypsum—does not even appear in the index. Moreover, as far as our search goes, no splints or suchlike appliances are described. This is obviously not a handbook of surgical handicraft, and the reader who looks for that will in most instances be disappointed. But it is a valuable work of reference on the surgical pathology of childhood, and contains an extraordinarily full and valuable bibliography. It is illustrated and printed in that sumptuous style which, despite their poverty, is still available to German men of science.

[3] *Chirurgie des Kindesalters.* Von Professor R. Drachter und Dr. J. R. Gossmann. 3, völlig umgearbeitete und vermehrte Auflage. Leipzig: F. C. W. Vogel. (Pp. xvi + 1031; illustrated. M.125.)

RADIATION THERAPY

Dr. IRA KAPLAN'S volume, entitled *Practical Radiation Therapy*,[4] gives a general outline of what can be accomplished by *x* rays, radium, and endothermy. It commences with a brief historical account of *x* rays and radium, followed by a chapter on the elementary physics of the subject. Chapters on dosage and equipment are followed by details of the application of these methods to cases of every variety.

The cases are well described and profusely illustrated, and within the limits of the book the details given are reliable. The book undoubtedly provides an excellent bird's-eye view of the whole subject, but we feel that the author has really attempted to compress too much into the space at his disposal. There is scarcely a human ailment for which *x* rays are not suggested as a cure, and the headings of "Asthma," "Pertussis," and "Malignancy of the nose," taken at random, will illustrate the extent to which the author's faith has carried him. Those who know nothing about the subject will, however, discover the immense range and power of modern physical methods, while those who are expert will be stimulated by some of the cases which are described. The book, like all Messrs. Saunders's, is magnificently presented, and the illustrations are admirable.

MEDICO-LEGAL ASPECTS OF HAIR

From time to time cases occur in medico-legal practice in which considerable importance is attached to the recognition of hairs and fibres. In charges of criminal assault and in murder, fragments of hair may be found on a weapon or in other circumstances in which the identification of their source may be of vital importance. An example was the famous Crippen case, in which the identification of a few hairs alleged to be those of Belle Elmore was of the utmost value, as was a decision relative to the presence or absence of hair follicles in an alleged scar in a fragment of abdominal skin. More recently, in the trial of Podmore for murder at Southampton, the identification of a hair found on a hammer as an eyebrow hair of the victim had a certain importance, and in the Rouse trial there was a controversy over the origin of certain hairs found on the weapon with which the assault was supposed to have been committed. Many other cases could be quoted to show the importance of a knowledge of the distinguishing characteristics of hairs.

Although there are a number of textbooks or atlases in foreign languages devoted to a study of hairs, there

[4] *Practical Radiation Therapy.* By Ira I. Kaplan, B.S., M.D. With a special chapter on Applied X-Ray Physics by Carl B. Braestrup, B.Sc., P.E. Philadelphia and London: W. B. Saunders Company. 1931. (Pp. 334; 227 figures. 27s. 6d. net.)

has been a singular lack of such books in English. This gap has, to a certain extent, been filled by the publication of a study of hairs in the mammalian group of animals, including a special study of human hair, by Professor John Glaister, jun.[5] The book contains a hundred and ten plates of animal hairs and thirty-four plates of illustrations of human hair, each plate containing a number of photomicrographs. The author has used actual photomicrographs throughout, and numbers of hairs are shown, not only in longitudinal plane, but in cross section. Many of these illustrations are very good indeed, and some of them should help in the recognition of hairs, but, as the author himself points out, no pictorial representation is of much value in actual identification. A very large number of the illustrations show nothing whatever of the structure of a hair—for example, the eight photographs in Plate 2 and others throughout the atlas; many such illustrations could be left out without detracting from the value of the book.

The work is arranged in nine sections. After a brief description of the process of section-cutting and photography, the author discusses the zoological classification of animals, and gives a general description of the coats of animals and the macroscopical appearances of their hairs. This section, which occupies about forty-eight pages, is very sketchy and devoid of scientific interest. The microscopical appearances of hairs in a longitudinal plane are then described, followed by a description of the microscopical appearances in transverse section, each order being dealt with in turn. This section is the best part of the book, some of the illustrations being distinctly valuable. Section V is a dissertation on the value of the described appearances in identification, again dealing with orders, sub-orders, and families. This method of description is most puzzling to the reader, who has to consult three different parts of the work for the description of a certain hair, and then two other parts for the illustrations in longitudinal plane and section. As there is no index or reference of any kind, the task of looking for the description of any particular hair is extremely difficult.

The author says: "In securing a photographic atlas showing the common appearance of the hairs and wools of the mammals, one of the chief objects of this work has been accomplished." If this is his chief aim we have nothing but commendation, but if the object is also to present a work of value in identification of hairs, then considerably more attention must be paid to details. Certain of the claims advanced rather detract from the value of the work; for example, we read that "it is possible to express an accurate opinion regarding the sex from which hairs have been derived only under certain circumstances." We agree only if "certain circumstances" other than the hair prove the sex, for the differences between hairs of different males may be much greater than the differences between male and female hairs. A further claim is made that from the description of the characters of animal hairs in the atlas the identification of the order, sub-order, and family may be made, but we have searched in vain for any systematic scheme of identification of order, sub-order, or family which would render this possible.

A rearrangement of the book to enable the reader readily to find what he seeks, the introduction of an index, and a careful re[illegible] breathing. [illegible]e text, should render this [illegible]work of infi[illegible] has [illegible] a pretty normal health, but even as it is we con[illegible]an exceptionally fine athlete [illegible] production of a volume enough, he had some consciousn[illegible] of an enormous amount tion, as he was wont to observe[illegible]s kind in the English differently from other people." A[illegible] the position of his heart on the right by his doctor many years ago.

PHYSIOLOGY OF THE CELL

A Text-Book of Experimental Cytology,[6] by James Gray, is a stimulating production. It is stated in the preface that the book, which represents the substance of a series of lectures, "was planned as a convenient means of introducing to students some conception of the complexity of ideas which arise from the study of the simplest of morphological units." It is largely an attempt to correlate cellular with physico-chemical phenomena, but the author is careful to warn us at the outset "that no single activity of the living cell has yet been analysed in physical terms."

The opening chapter is concerned with the cell as the unit of life. The cell is next considered as a physical unit, and it is shown that great caution must be exercised in applying the statistical laws of physical chemistry to a biological system. A discussion of cell dynamics is followed by an account of the cell as a colloidal system, a conception which "is probably one of the most important landmarks in the history of cytology." The physical nature of protoplasm and the properties of cell membranes and intercellular matrices are dealt with at some length; the author then gallantly but despairingly tackles the problem of the nucleus. The nucleus, he admits, has so far defeated all attempts at physico-chemical interpretation, and he confesses that "it seems impossible to point to any inanimate system (endowed with the known chemical or physical properties of the nucleus) which in any real way possesses the requisite complexity whereby it might reflect even feebly the biological facts." An interesting review is given of the work relating to some of the complex problems associated with the mitosis, division, shape, growth, and individual variability of cells, and with the equilibrium between the living cell and water. The important question of the permeability of the cell surface is discussed, and we find that it is impossible to prepare any inanimate structure which will resemble the cell surface in possessing the same power of allowing the passage of some substances and preventing that of others. "It is the specific nature of the cell surface which enables a living cell to maintain within itself the equilibrium which is essential to life," and it is therefore not surprising to learn that the nature of this surface is very imperfectly understood. The theoretical significance of such phenomena as the motility, respiration, and survival of spermatozoa, fertilization, and artificial parthenogenesis, is considered in a chapter on the germ cells; the final chapter is concerned with a discussion of the mechanism of contractility (muscular, amoeboid, and vibratile) and of phagocytosis.

The volume is to be strongly recommended to everyone interested in the physiology of the cell. From the reader's point of view the value of the data quoted is greatly enhanced by the careful and temperate criticism with which they are set forth. The author has presented his material from the mechanistic standpoint, because he considers that the mechanistic hypothesis has led "to a more orderly conception of biological data" than any other. Nevertheless, his treatment of the subject-matter is delightfully impartial, and the most uncompromising vitalist will surely admit that difficulties in interpretation are never minimized and that analogies are not overstressed. The fact is continually emphasized that our present knowledge of physics and chemistry carries us only a very short way towards a proper understanding of even the simplest cellular phenomena. We cannot but feel, however, that distant as we are from that ultimate goal of the mechanist

[6] *A Text-Book of Experimental Cytology*. By J. Gray, M.A., F.R.S. London: Cambridge University Press. 1931. (Pp. x + 516; 205 figures. 25s. net.)

—the complete interpretation of cell activity in terms of physics and chemistry—yet a considerable body of facts now exists concerning the physico-chemical properties of the living cell.

Mr. Gray's admirable exposition of the complexities and difficulties of the subject makes it clear that, at present, the only rational attitude towards cellular physiology is to be content to accumulate facts, and to formulate general theories only as a basis for further experimentation.

NOTES ON BOOKS

The appearance of a sixth edition of Beaumont and Dodd's *Recent Advances in Medicine*[1] is a sufficient measure of its popularity. Since its publication in 1924, twenty-two new volumes have been added to the Recent Advances Series, fifteen of which have dealt with the new knowledge in the special departments of medicine. In future "Beaumont and Dodds" will stand in much the same relation to these other works as philosophy does to the sciences which have separated from it. Therefore it seems that the volume will have to be planned on broader lines. Its scope will have to be wider. In the chapter on the heart the electrocardiographic changes occurring in coronary occlusion and in angina are not shown, while those that are represented can hardly be called recent. In a book of such general appeal the inclusion of so much biochemical detail, and of such tables, for example, as those for the estimation of basal metabolism, is of doubtful value to the student for whom the information is intended. Anyone performing routine estimations of basal metabolism will have his own special book of reference. Again, while sixty-four pages are devoted to special examinations and analyses of blood and urine, there is no mention of the important modern work on vitamins; the word vitamin does not even appear in the index. In the section on fevers no comment on the serum treatment of measles is made. "Beaumont and Dodds" is still an invaluable guidebook to newer medical knowledge, and is indispensable to the student working for higher medical examinations; but some revision of its plan would seem to be called for in view of its numerous progeny in the Recent Advances Series.

The second volume of the forty-first series of *International Clinics*[2] contains a remarkably large number of interesting papers by well-known writers relating to clinical medicine and surgery, medical ethics, syphilology, and hygiene. From these we may draw attention to the following: The present status of the post-operative pneumopathies, by Rudolph Matas of Tulane University, New Orleans; Widal and his work, by Pasteur Vallery-Radot; Bronchoscopy in the treatment of pulmonary diseases, by Chevalier Jackson of Philadelphia; Eye infections of dental origin, by O. Bjerrum of Copenhagen; The non-heredity of disease, by James J. Walsh of New York; Fever therapy in the treatment of syphilis, by J. F. Schamberg; and Syphilis as a problem in preventive medicine, by J. H. Stokes of Philadelphia.

In his medico-historical study of *The Girdle of Chastity*,[3] Mr. Eric John Dingwall, whose work on male infibulation was reviewed in these columns in 1925, has given a richly documented account of this instrument from its introduction in the twelfth century, when it was frequently applied to their wives by the Crusaders before their departure for the Holy Land, down to the present day, when, according to Mr. Dingwall, inquiries are still occasionally made for it of surgical instrument makers in London. A special chapter is devoted to an account of a Dr. John Moody, who published in 1848 a work entitled *A Medical Treatise with Principles and Observations to Preserve Chastity and Morality*, in which he described a special girdle for the prevention of masturbation and seduction. Chapters are also devoted to the forensic importance of the girdle of chastity and allusions to it in the literature from the fifteenth to the twentieth century. The text is illustrated by various types of girdles, of which the best known is in the Musée de Cluny, Paris.

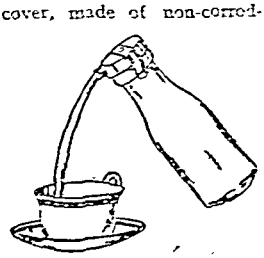
PREPARATIONS AND APPLIANCES

A Tube for Delivering Oxygen during Anæsthesia

Dr. J. B. H. Holroyd (anæsthetist, Sheffield Royal Infirmary) writes: I think that most anæsthetists will agree that there are a certain number of anæsthesias where a slight deficiency of oxygen makes all the difference between a peaceful and a very stormy passage. Hitherto this deficiency has been made up by simply passing a rubber tube from the oxygen cylinder under the anæsthetic mask. This tube has a habit of slipping about under the mask, and in most cases the oxygen blast has been delivered against the side of the mask, the patient getting the supply of oxygen on the way in a most haphazard manner.

I have devised a tube with a view to the patient getting the full advantage of the oxygen blast. This tube consists practically of two parts. One part is horseshoe-shaped and



flattened, having on the inner side a series of holes to allow of the delivery of oxygen. The tip is blind, on the same principle as a gas-ring burner. This part rests round the hole for the mouth and nose in the Gamgee tissue. It is obvious that each of the holes delivers a jet of oxygen as near to the mouth and nose as possible. This makes it certain that the patient is getting a substantial amount of oxygen. The other part of the tube is roughly an angular turn of the first part, and is attached to the tube from the oxygen cylinder, and at the same time, by its position, is out of the way of the administrator. The tube may also be used for delivering anæsthetic vapours, either alone or with oxygen.

The tube was made for me by Mr. T. W. Tyler, 65, Scott Road, Sheffield, to whom I am much indebted for carrying out my instructions.

A Milk-bottle Cover

The "tru-por" milk-bottle cover, made of non-corrodable aluminium with a rubber washer, does away with the difficulty of pouring milk from the ordinary milk bottle. It can be clipped in a moment on to the mouth of the bottle after removing the dairyman's cardboard cap, thus converting it into a covered milk jug with a pouring spout. The price is 1s. 6d., and the manufacturers are "Tru-Por," 6, Finsbury Square, London, E.C.2.

An Adhesive Bandage

Messrs. Cuxson, Gerrard and Co., Ltd., surgical dressing makers of Oldbury, Birmingham, have prepared a self-supporting resin bandage ("ceraban") for the after-treatment of varicose veins, and for sprains, dislocations, and contusions. While free from rubber, this adhesive bandage possesses elastic properties, and when carefully applied to a limb it gives substantial support.

HEALTH OF LONDON SCHOOL CHILDREN

REPORT FOR 1930

In his report for 1930 on the health of London school children,* Dr. F. N. Kay Menzies, County Medical Officer of Health and School Medical Officer, states that there has been a continued and progressive development in almost every branch of the School Medical Service. He claims that the physical condition and comfort of the children has never been better, judged by the figures relating to personal hygiene and nutrition.

Entrant Children

On entering school, children are found to present a large number of defects. One-half of them have carious teeth; 10.3 per cent. of entrant boys and 9.2 per cent. of entrant girls are referred for treatment for enlarged tonsils and adenoids, as compared with 5.7 per cent. of the 8-year-old and 3.6 per cent. of the 12-year-old children. Other conditions from which the entrants suffer to a much greater degree than the older children are ear discharge, external eye disease, lung trouble (chiefly bronchitis of rickety origin), and rickety deformities.

A special examination was made of 1,638 unselected children, aged 5, in thirty-three London elementary schools by three medical officers, who confined their examination entirely to the detection of nine bony abnormalities commonly associated with rickets; three or more signs of rickets were found in percentages varying from 25.9 in "fair" schools to 50.2 in "poor" schools. The conclusion drawn is that much improvement is still required in housing conditions and in training in motherhood. In a digital examination of 1,361 of these children, 174 (12.8 per cent.) were found to have been already operated on for the removal of adenoids. Of the remainder, the nasopharynx was normal in only 237 (17.4 per cent.); tonsillar enlargement with or without sepsis was present in 193 (14.3 per cent.), and tonsillar sepsis without enlargement and without adenoids was found in 10 (0.7 per cent.). Adenoids, with or without tonsillar enlargement, were present in 747 (54.9 per cent.). It is noteworthy, in contrast to the distribution of the signs of rickets, that the proportion of children free from adenoids was highest in the poorest group of schools. The importance of digital examination for adenoids was brought out by a subsequent re-examination of 490 of these children by the same observer about a year later, in which he recorded only symptoms related by the parent or teacher and those observed by himself without a digital examination. With digital examination, 30 per cent. of the mouth-breathers showed no signs of adenoids, [illegible]e of those showing extensive adenoids only 29.3 per [illegible] were mouth-breathers.

possib

from

Examination of Leavers

circum.Council has voluntarily instituted for a 14-year age stances [illegible] examination, which takes place in the differences[illegible]ious to [illegible] that in which the children are due to greater t[illegible]ool. Consi[illegible]erable improvement was found in hairs. A[illegible], as compa[illegible]ed with the 12-year-old group, in of the char[illegible]personal hyg[illegible]ene, visual acuity, tonsillar and tion of the [illegible]owths, otorrhoea, anaemia, and heart defect. [illegible] boys the incidence of spinal and other deformities was also distinctly less, but among the girls these deformities were found in increased ratios. Great care is evidently necessary in the case of girls, aged 12 to 16, who are growing rapidly, to correct faulty postures and give periods of recumbent rest.

Other points of interest are that, for the last three or four years, there has been a greater readiness to have enlarged tonsils and adenoids treated; this has resulted in a smaller number of cases of discharging ears, and an improvement in hearing capacity. In view of the unsatisfactory nature of the tests of hearing in general use, trial has been made of the "audiometer," a gramophone fitted with a magnetic pick-up, which enables the sound to be transmitted to a number of single head-phones; as many as forty children can be tested at the same time. All children requiring operations for tonsils and adenoids are now dealt with as in-patients, being kept at centres or hospitals for two nights after the operation.

With regard to the health of pupils in secondary and trade schools, where deterioration of the teeth and of vision has been found to occur in the children from 12 to 15, principals and parents are advised to ensure the payment of regular visits to the dentist and oculist.

Basement Children

A special inquiry was made into the medical history, physical condition, and school history of 254 children living in basements, two comparable children not living in basements being examined with each basement dweller. A history of diphtheria among children living in basements was twice as frequent (5.1 per cent.) as that among the controls (2.5 per cent.). At most ages the former compared unfavourably with the latter in height and weight. Basement children were not so well nourished, 35.7 per cent. being definitely under-nourished, compared with 19.1 per cent. of the control group. Throat and nose affections were found in 7.4 per cent. of the basement dwellers and in 3.3 per cent. of the controls. Symptoms of rheumatism were found in 2.2 per cent. of the children living in basements and in 0.8 per cent. of the non-basement children. The educational inquiry revealed that fewer children living in basements were making normal progress at school than among the children selected as their controls; the head teachers returned 43.6 per cent. of basement children and 24.8 per cent. of the controls as definitely backward; 11.8 per cent. of the basement dwellers and 5.9 per cent. of the controls were irregular in their attendance at school.

Delinquent Children

During the year 785 children were admitted to the Ponton Road place of detention. In view of the general impression that most of such children are mentally defective, it is interesting to learn that, while serious mental retardation was present in the majority, only 7.5 per cent. of 695 examined were found to be certifiably mentally deficient. For educational levels Professor Burt's standardized reading and calculation tests were used, and the Stanford revision of Binet's scale and Healy's form boards to estimate mental ages. In addition, a careful Porteus maze test was made in most of the cases; it serves as a test of intelligence as expressed in the form of practical ability as distinct from intelligence which requires for its expression the use of verbal imagery. A comparison of the mental, educational, and Porteus levels brought out clearly the failure of achievement; while judged by their mental levels 26.2 per cent. were up to or above their chronological age, only 10.5 per cent. had reached this level as regards their educational attainments, and 8.8 per cent. as judged by the Porteus maze test.

The physical condition of the delinquents was very inferior to that of the average London school child; this inferiority is in some degree inherent, but much of it is acquired and capable of being remedied. A careful examination for congenital syphilis, often held responsible for delinquency, failed to give evidence of this condition in more than 0.9 per cent. of the children. The very indifferent physical make-up of the delinquent has little direct bearing on the delinquency, but sheds a flood of light on the environment in which he lives. Psychotherapy has only a very limited field in child delinquency. The home and school environments contain the key to the solution of the majority of child delinquent cases; here there is a valuable field for the social workers of child guidance clinics.

Ophthalmia

A feature of the year was the transfer of twenty-three schools or children's homes from the former Poor Law authorities to the L.C.C. Education Committee. Arrange-

* London County Council. Annual Report of the Council, 1930. Vol. iii (Part ii). Public Health (Report for the year 1930 of the School Medical Officer). London: P. S. King and Son, Ltd. 1931. No. 2851. (1s. 6d.)

ments were at once made to standardize the medical supervision and treatment. Several cases of trachoma occurred in one of the residential schools and in a large philanthropic orphanage, the managers of which welcomed the assistance of the London School Medical Service. Subsequently at the orphanage all the 360 children were inspected; 93 were suffering from some form of conjunctival disease, mostly "follicular conjunctivitis." Of these, 18 showed signs of granular conjunctivitis suggestive of trachoma. On being seen by Mr. Bishop Harman, two were sent to the White Oak Hospital, Swanley, as suffering from trachoma; the remainder were treated at the orphanage. No child requiring treatment was allowed to take up swimming unless specially permitted.

At the Anerley Residential School, of 564 children, 190 were affected with some form of conjunctival disease. Of these, ten were admitted to Swanley as cases of trachoma. Extreme care is taken to ensure the use of clean towels in this school. Immediately after use each towel is placed in a receptacle and taken to the laundry, and no towel (face or bath) is used a second time unless it has been washed. Liquid soap is used instead of a common piece of soap. Every child has fresh water for washing and bathing; the water of the swimming bath is changed and the bath thoroughly cleansed once a week.

Rheumatism

Rheumatism now takes the first place among diseases which produce chronic invalidity in the children. An analysis of 1,028 attacks of all forms of rheumatism—rheumatic fever, subacute rheumatism, and chorea—shows that attacks are more evenly distributed throughout the year than is generally thought. Although the first and last quarters of the year are usually accepted as the peak period for rheumatism, 41 per cent. of the rheumatic attacks occurred in the second and third quarters; this means that pressure on the available beds is heavy throughout the year. Another valuable figure for administrative purposes, deduced from the statistics available, is that there are roughly three rheumatic girls to two rheumatic boys. On an examination of the history of 1,709 rheumatic children, it was found that 11 per cent. of the first attacks occurred in the 6 to 7-year-old period, and 29 per cent. in the 7 to 8 age period. Of 1,287 children treated in hospital, 11.6 per cent. suffered from rheumatic fever, 60.9 per cent. from subacute rheumatism, and 27.5 per cent. from chorea.

Two sets of statistics are given which throw some light on the proportion of rheumatic children in whom the heart is attacked. In children suffering from rheumatism of a severe nature and discharged from Carshalton or Brentwood, 55 per cent. of the total number (1,325) had heart disease; in 26 per cent. of the total valvular disease had been established. A more valuable figure is that obtained from the rheumatism supervisory centres, which include children affected by the milder manifestations of the disease, in addition to others who have been more severely attacked. Of 1,529 children diagnosed as definitely rheumatic, the heart was affected in 41 per cent., and valvular disease of the heart was present in 14 per cent.

The value of prolonged hospital treatment has been brought out by Dr. Warner, who pointed out that although the cases sent to Carshalton were initially more severe than those treated by other methods, the relapses in the first three years represent only half the number met with in cases which have not had prolonged institutional treatment.

Practically all these rheumatic children are forbidden to swim for a time after their return from hospital. Of 810 children discharged from hospital with normal hearts, 65.4 per cent. returned to an elementary school with no restrictions, 24.3 per cent. were not allowed to drill or play games, 8.4 per cent. were sent to a school for the physically defective, and 1.9 per cent. were invalids. Of the 272 children discharged with the heart affected, the corresponding figures were 11.8, 23.2, 62.1, and 2.9 per cent.

At the Hammersmith supervisory centre, Dr. Gerald Slot finds that the greatest difficulty is to get the parents of patients in early cases to realize the importance of rest and longer sleep at night. In view of the fact that once children are known to be definitely rheumatic, they are never free from a risk of further manifestations, Dr. T. W. Preston does not discharge them from the supervisory centre until they leave school; the children are seen at intervals of six or twelve months to make sure that they are still well. As regards the children brought to the centre whose condition is doubtful, he has gained the impression that many improve as the result of milk and cod-liver oil given in school; in those cases in which glucose has been recommended, the results have been less successful than some modern teaching would lead one to hope.

Small-pox

During the year 1,774 children were notified as suffering from small-pox; the total number notified in London at all ages being 5,149. The greatest incidence occurred in the north-eastern division, where 1,124 cases of children were notified. Two deaths occurred, the causes of the first being reported as (*a*) encephalomyelitis, (*b*) small-pox; and of the second (*a*) pyaemia, cause unknown, (*b*) small-pox discrete modified. In the majority of cases, children suffering from small-pox had not attended school in an infectious condition. When there was any evidence of the possibility of spread of infection in the school, a special examination of the children in the school was made by one of the assistant medical officers, and the affected schools were visited daily by the school nurses for a period of nineteen days from the date of attendance of the last case in the school; as a result of their reports 128 cases were notified. The home contacts of cases of small-pox were allowed to return to school, provided that arrangements could be made for their daily examination in school by the school medical or school nursing staffs. Later in the year, by the engagement of extra nursing staff, practically all the contacts were enabled to attend school.

Facilities for vaccination on the school premises by public vaccinators were granted whenever applications for vaccination were received from the parents. Comparatively few applications were sent in, and only about 300 children were vaccinated with the written consent of the parents. In another part of the report, however, some evidence is forthcoming that when small-pox occurs in an area where vaccination in infancy is commonly neglected, a number of school children are given the protection of vaccination. The proportion of leavers vaccinated in four out of five London boroughs where small-pox was especially prevalent in 1928 is greater than the percentage of entrants vaccinated; for the five boroughs the comparative percentages are 50 and 53.

Diphtheria Carriers

In all, 128 persistent carriers were dealt with at the special clinics established for the treatment of diphtheria carriers at the London, St. Mary's, and Guy's Hospitals. Dr. John Eyre emphasizes once more the insufficiency of one routine swab as a means of detection of carriers. Diphtheria bacilli, when not revealed in first smears made from twenty-four-hour inspissated serum slopes, were sometimes found when plated on Douglas's differential medium. At Guy's Hospital persistent carriers with negative nasal swabbings are found to clear up rapidly after tonsillectomy. A case is recorded of a nasal carrier of twelve months' duration in which the routine examination on the first visit to the clinic revealed a foreign body in the nose; after removal of this body and healing of the ulceration the swabs became negative. Vaccine therapy was used with good effect at all three clinics.

The association of members of the Chartered Society of Massage and Medical Gymnastics in private practice has published a new edition of its directory giving the names, addresses, and qualifications of members, and the work they are prepared to undertake. They have adopted regulations which pledge them to work only under the direction of a registered medical practitioner. Medical practitioners may obtain copies (post free) from the secretary of the Private Practitioners' Association, Hygeia, Falmouth, Cornwall.

British Medical Journal

SATURDAY, OCTOBER 3rd, 1931

DOSAGE OF DIPHTHERIA ANTITOXIN

During the past thirty-five years probably some millions of patients have been treated with diphtheria antitoxin, a medicament whose specific activity can be measured with reasonable precision ; yet even to-day the proper dosage is unsettled. The clinician, with scientific humility, will wonder how firmly founded are many of our ordinary medical practices and beliefs if in this field, with its incomparable wealth of clinical data, we have not reached agreement. In the treatment of diphtheria the dosage recommended ranges from 2,000 units in a mild infection (Goodall) to 300,000 in a severe attack (Bie). What is the reasonable *via media* which the conscientious physician can follow?

When faced with a patient suffering from diphtheria we are bound to ask how much of the specific toxin of the diphtheria bacillus is still in the circulation and therefore accessible to attack by antitoxin, how much is already intracellular and therefore wholly or almost wholly beyond reach of antitoxin, and, lastly, how much damage has already been done to tissue or function, and whether any of this damage is remediable. We know that very little antitoxin is necessary to prevent the ingress into the circulation of further toxin produced by the bacilli in the throat. A human being naturally immune and negative to the Schick test, whose total blood contains perhaps as small a quantity as 200 units of antitoxin, is safe, even if virulent diphtheria bacilli lodge on the tonsil. There are a few observations which will help us to decide how much toxin a patient may have absorbed. It is known, as the result of unfortunate accidents in the early history of active immunization against diphtheria, that approximately thirty times the minimal amount of toxin that would be lethal for a guinea-pig will kill susceptible children in three to six days, and that about 300 lethal doses may kill children within twenty-four hours. This line of argument would suggest that a moderate number of units of antitoxin given intravenously would be sufficient to neutralize the total amount of toxin present in the average patient and still susceptible to attack by antitoxin. There still remains for consideration toxin already intracellular and united with the tissue. Here, a pretty series of experiments by Glenny and Hopkins are helpful. These workers injected intracutaneously into guinea-pigs a small dose of toxin sufficient to produce an inflamed area nearly an inch in diameter, appearing in about eighteen hours. They inquired what multiple of the amount of antitoxin (which would, if mixed with the toxin, completely neutralize it) must be injected at intervals after the toxin in order to prevent the appearance of the skin reaction. If given intravenously seventy minutes after the toxin, 50,000 multiples would not completely prevent the reaction, nor would 500,000 multiples when injected eighty-five minutes after the toxin. This amount of toxin, therefore, had entrenched itself impregnably in the cells within an hour and a half. In another series, 10 million multiples of antitoxin given intravenously four hours after the intracutaneous injection of toxin could not suppress the reaction. It proved impossible to save the life of an animal if antitoxin was delayed for two hours. It is reasonable, therefore, to conclude that no practicable excess of antitoxin can overtake toxin which has had a few hours' start. The clinician cannot well avoid the thought that but little time is granted him for the immediate administration of the one effective dose which will neutralize the toxin—accumulated but still accessible—and save his patient, if he can be saved ; and that controlled laboratory experiment offers no justification for dividing the effective quantity of antitoxin into separate doses to be given at intervals. In the researches mentioned above there appears also a striking illustration of the well-known superiority of intravenous over subcutaneous administration. A dose of 1,000 units of antitoxin, if given subcutaneously half an hour before the intracutaneous injection of toxin, reduced the reaction to half the expected size, whereas one-hundredth of the amount of antitoxin—that is, 10 units—given intravenously even half an hour after the toxin was equally effective.

With a knowledge of these facts, and with the mass of clinical experience now available, how can we decide what is to be the effective dose? The route will be intravenous or intramuscular, and not subcutaneous—whether we agree or not with Banks that "a haphazard subcutaneous injection of serum is equivalent to postponing operation on a gangrenous appendix for three days." The experienced man with facilities available tends to choose the intravenous route in all severe and even moderate attacks, though the Ministry of Health, with the general practitioner in mind, does not consider that there is justification for the general use of the intravenous method. The Ministry emphasizes early and adequate dosage, and suggests a minimum of 8,000 units in mild attacks seen early, and a maximum of 30,000 units for a patient severely ill, admitted late in the attack. American practice is represented by Stimson's range—from 5,000 in a very mild attack to 25,000 injected intravenously in severe cases. If this dosage is doubled for the intramuscular route, we approach the scale of 5,000 to 60,000 quoted by Ker and by Park. Banks and McCraken have recently urged intravenous dosage up to 140,000 units in severe attacks, and Bie in Copenhagen has given 300,000. Probably the moderate man will conclude that the recommendation of the Ministry of Health is a good general guide, and will give 8,000 to 10,000 units intramuscularly to the patient with a mild attack, and 30,000 to 50,000 units intravenously to the child desperately ill, the ever urgent indication being for early administration. The attempt to see what damage to tissue and function is remediable is outside our present discussion.

The Beit trustees recently commented on the increasing number of Fellows who choose the indirect attack on microbic disease by research in biochemistry Specialists in infectious fevers will welcome the help of the biochemists and pharmacologists who are now investigating the disturbed metabolism of diphtheria, promising results from the use of glucose and insulin are already being recorded In investigations of this kind lies the hope of further reduction of mortality in attacks of diphtheria already beyond the reach of antitoxin treatment

DIET AND CARIES

The Committee upon Dental Disease working under the Medical Research Council, has just issued an interim report on the influence of diet on caries in children's teeth[1] In the introduction to this pamphlet it is explained that the Council is publishing a series of reports describing Mrs Mellanby's work on diet in relation to the development of the teeth and jaws Two of these reports, which set forth the results of Mrs Mellanby's experiments on animals have already been noticed in our columns and a third report by the same author, describing the effects of diet upon human teeth, will be published sometime during the next few months The knowledge obtained from this experimental work appeared to the Medical Research Council to be of such great practical significance that it was determined to test the powers of this new weapon of preventive medicine by a large scale trial Such an investigation was organized in Birmingham in 1927 and the Council considers that the results already obtained in this trial justify the publication of an interim report

The investigation, which was carried out under the supervision of Mrs Mellanby and Dr Langdon consisted in studying the influence of the addition of vitamin D to the diet of children living under uniform conditions The children who numbered about 800, and were of ages from 2½ to 16 years, lived in residential institutions in Birmingham Two series of investigations were made In the first series three groups of children, each living in a different institution, were studied The additions to the diet were as follows one group received about an ounce of treacle daily, a second group about half an ounce of olive oil, and a third group about half an ounce of cod liver oil In the second series two groups of children in the same institution were compared One group received olive oil and the other group olive oil to which irradiated ergosterol had been added (the preparation used was radiostol which was supplied free of charge by British Drug Houses) The teeth of the children were examined every six months, and the report deals with observations extending over two years Continuous observations were made on about eighty children in each group

The question which the present report seeks to answer is "Can the incidence and rate of progress of caries in teeth already erupted be lessened by the adoption of dietetic measures?" The results published by Mrs Mellanby and her fellow workers show that "In groups of children, numbering from sixty five to eighty six, living under similar institutional conditions, each group receiving a certain specific addition to the standard dietary, over a period of two years, the progress of caries in the permanent teeth has been significantly retarded in those children receiving an added ration of fat soluble vitamins as compared with those whose additions consisted of treacle and olive oil respectively the increase of caries in the vitamin group whether measured by its incidence or its extent being approximately one third of that in the other groups" Moreover the second investigation shows that administration of irradiated ergosterol led to a correspondingly favourable result

The report is short and inexpensive—less than twenty pages at the price of 6d—but it contains full statistical details of the figures on which the authors conclusions are based and should be studied by all who are interested in the hygiene of childhood It is an interim report, and deals with results produced in the short period of two years but the hope may reasonably be entertained that more prolonged treatment along the same lines will yield even more striking results The evidence already obtained shows however that the incidence and the degree of dental caries in children can be greatly lessened by simple dietetic measures, hence it follows that this disability so common as to be almost universal among our people must be regarded as a disease that is at least in part, preventable The organization and the prosecution of long-drawn-out observations on the scale of those described must have been costly both in time and in labour, and those who took part in the inquiry at Birmingham are to be congratulated on the fact that their efforts have produced results of great potential importance for the future health of the nation

NUTRITIONAL ANAEMIA IN INFANCY

During the past five years Dr Helen Mackay and her colleagues have been making an investigation into the prevalence, etiology, and prevention of anaemia in young babies, and the results of this extensive research are now published,[2] together with a statistical analysis of the data by Dr A Bradford Hill A review of the literature of anaemia in infancy shows that there is no general agreement concerning cause course or treatment whether the infants considered be premature or full term Some hold that the anaemia of the full term infant is analogous to the chlorosis of adolescence others that it is due to the toxic effects of cow's milk others that it is secondary to a variety of factors—such as infections and dietetic error—while a few others,

[1] Medical Research Council Special Report Series No 158 The Influence of Diet on Caries in Children's Teeth (Interim Report) By the Committee upon Dental Disease London H.M Stationery Office 1931 (6d net)

areas shows that these are now lower in the towns than in rural districts in Germany, Switzerland, Holland, Belgium, Sweden, Finland, and Bulgaria. In Italy the mortality in rural districts is now exactly the same as in the towns, and the rural mortality is only a little lower than the urban in England and Wales, Denmark, and Norway. At the present time only France, Spain, Hungary, Scotland, and the Irish Free State show a fairly marked urban excess. Although formerly infantile mortality was much higher in towns than in the country, it is now almost everywhere in Central Europe lower in towns than in rural districts. In Southern Europe, on the contrary, there seems to be little difference between urban and rural infant mortality, and in England and Wales both the birth rate and infantile mortality are higher in towns than in rural districts. After the age of 40 the urban death rates are everywhere higher than the rural death rates, but in youth, especially in the case of the female sex, the position of the rural population in this respect is in most countries unfavourable. Tuberculosis generally causes a higher mortality among young women in rural districts than in towns, and more deaths are due to respiratory diseases, including whooping-cough, in rural districts than in towns. The maximum death rates for the other epidemic diseases of childhood occur later in life in rural than in urban areas. It should, however, be borne in mind that the notification of infectious diseases is almost invariably less complete in rural districts.

FARADAY'S OBSERVATIONS ON MENTAL INERTIA

In the British Association Centenary Number of *Discovery* (for October) Professor D. F. Fraser-Harris contributes some interesting notes on the principle of mental inertia, with special reference to Faraday's conception of the subject. His remark that early in his career Faraday was thinking of *mental* phenomena in the most comprehensive terms is a timely one, since the impressive developments of Faraday's researches in physical science are apt to obscure the value of his speculations in other departments of knowledge. In a lecture entitled, "Observations on the inertia of the mind," which he delivered in his twenty-seventh year to the City Philosophical Society in London in 1818, Faraday declared:

> "There is a power in natural philosophy of an influence universal and yet withal so obscure in its nature, so unobtrusive, that for many years no idea of it existed. It is called 'inertia.' It tends to retain every body in its present state and seems like the spirit of constancy impressed upon matter. Whatever is in motion is by it retained in motion, and whatever is at rest remains at rest under its sway. It opposes every *new* influence and strengthens every *old* one. Is there anything in the human mind which seems analogous to this power? Is there no spiritual effect comparable to this corporeal one? . . . I have endeavoured to establish the analogy between habit of industry and the inertia of a moving body. I have said that the inertia of matter is continually blended with other forces which complex its results and render them apparently contrary to their cause, and also that in this respect it resembles the inertia of the mind."

Professor Fraser-Harris's article possesses also an extrinsic interest, for he expounded his own theory of inertia for the first time at the British Medical Association's meeting at Ipswich in 1900, unaware that Faraday had read a paper on the subject about eighty years before that date.

OLD MEDICAL BOOK CATALOGUES

The market for second-hand medical books published from the fifteenth to the nineteenth century is still flourishing, in spite of the world depression. These books were literally a drug in the market until quite recently. The catalogues announcing them were poorly printed on indifferent paper, or they were to be found in the 2d. or 6d. box outside the shop door as not worth the cataloguing. Times are now changed; from London, from Paris, from Amsterdam, from Leipzig, and from Vienna come quartos and large octavo volumes beautifully printed on excellent paper, gorgeously illustrated, and annotated. Books which are an education in themselves and deserve to be kept and bound if only one had room for them on one's shelves. But then the prices asked! Each catalogue has to be studied carefully as to its origin. All are marked in plain figures, as the shops say, but 4.50 gulden is very different from 4.50 lire, and 200 Swiss francs are by no means identical with the francs of Paris, nor is the reichsmark the equivalent of the Austrian schilling; so it behoves the buyer to be wary before he orders. He learns by experience when he has been thinking in francs and the bill arrives in gulden. It is like the lady who, attending the auction of antique silver, was simple enough to believe that she was bidding by the piece, when in reality she was buying by the ounce.

MEDICAL BRANCHES OF THE SERVICES

A note in the *Journal* of August 29th announcing the Educational Number, 1931, made brief reference to the present terms of service and remuneration of officers of the R.N.M.S., R.A.M.C., and R.A.F.M.S., and commended these Services to the notice of younger members of the profession. The wording of this sentence needs modification, in the light of recent events and decisions. Members will recollect that the Council of the British Medical Association issued three reports on the medical branches of the fighting Services (*Supplement*, April 25th, 1931, p. 152), pointing out improvements both in pay and in conditions of employment which the Association considers imperative if the medical services of the Navy, Army, and Air Force are to attract an adequate number of new entrants. These reports having been approved by the Representative Meeting on July 21st, 1931, the official policy expressed therein now obtains. The Association has presented documentary and oral evidence before the committee which was appointed by the Prime Minister to investigate the causes of diminished recruitment of medical officers to the fighting Services, and it is understood that this committee is now engaged in preparing its report.

Before leaving Scotland the King invested Dr. Alexander Hendry, Surgeon Apothecary to His Majesty's Household at Balmoral, with the insignia of Knight Commander of the Royal Victorian Order, and conferred on him the honour of knighthood.

BRITISH ASSOCIATION CENTENARY

SCIENTIFIC PROCEEDINGS

The British Association for the Advancement of Science continued its daily sectional meetings which began last week; a note on the first day's discussions in the Sections of Physiology and Psychology was published in our last issue. These two Sections have been dealing with various topics of medical interest, as also has the Section of Chemistry, and some of the more salient points deserve attention.

SECTION OF PHYSIOLOGY

Biological Nature of the Viruses

Dr. H. H. Dale, F.R.S., in his presidential address to the Physiological Section, introduced a discussion of the biological nature of the viruses by raising the question as to the minimum degree of organization which could be reasonably attributed to a living organism. He remarked that it was interesting to note that Edward Jenner was dealing with small-pox and vaccinia—characteristic virus infections—long before there was any hint of the connexion of visible bacteria with disease. Pasteur also was confronted by another typical example of a virus infection in the case of rabies. Since the pioneer observations of Ivanovski's work in 1892 on the mosaic disease of the tobacco plant, and Loeffler and Frosch's demonstration about the same time that the infection of foot-and-mouth disease was due to something microscopically invisible, which passed easily through ordinary bacteria-proof filters, the study of viruses had progressed until they were recognized now as the causative agents of many of the more serious infections of man, animals, and plants. Dr. Dale then proceeded to a critical examination of what had hitherto been considered the standard characteristics of a virus. Microscopical visibility was obviously a loose term, and, recently, progress had been rapid in the direction of bringing into the visible range minute bodies associated with an increasing number of viruses; such enhanced visibility had thrown doubt on the position of the Rickettsia group of infections, and the limit of the process of exclusion on such lines could hardly be forecast. Another line of criticism, while not insisting on microscopical invisibility, demanded more evidence that the minute bodies seen or photographed were real infective agents, and not merely products of a perverted metabolism due to such infection. The physical evidence obtained by filtration through porous fabrics and colloidal membranes, and by measurement of the rates of diffusion, was simply concerned with the size of the units of infective material, and had to be taken in conjunction with the microscopical evidence. There was no fixed limit of filterability now; the only proper use of a filter in this connexion was to give a quantitative measure of the maximum size of the particles which passed through it. The third negative characteristic of a virus—namely, its failure to propagate itself except in the presence of living cells which it infected—might obviously provide another unstable boundary, shifting with the advance in knowledge and technique. A good example of the central difficulty which was to be tackled by the discussion was the action of the herpes virus, one conception of which was that it was a distinct ultra-microscopic organism, the person liable to attack being a carrier in whom the virus could be awakened to pathogenic activity and multiplication by injuries which weakened the normal resistance of his cells to such an invasion. The other conception regarded the virus as a pathogenic principle produced by the cell in response to injury, and awakening other cells to further production when transmitted to them.

Dr. Dale hoped that, even though they might be forced to the conclusion that some viruses consisted of units too minute to be classed as living organisms, they might avoid an alternative conception which referred to them as "enzymes." No evidence was available that any enzyme had the properties of a virus, or that any virus had those of an enzyme. The virus might be regarded as a transmissible toxin when it caused the infected cell to disintegrate, or as a transmissible stimulant when it induced an abnormal proliferation. In either case the special characteristic of a virus must be postulated as a power of imposing on the cell which it infected an altered metabolism, which led to its own reproduction. The study of infection during the past century had resulted in its becoming the epoch of the visible bacteria; the new century seemed likely to be an epoch of no less important discoveries concerning the viruses.

Dr. T. M. Rivers said he preferred a positive characterization of the viruses, which would emphasize the intimate relation between them and their host cells, rather than the negative characterization by their properties utilized by Dr. Dale. If it was true that viruses could be cultivated on lifeless media, they were autonomous living agents, but it was doubtful at present whether this conclusion could legitimately be drawn from the data, which, though numerous, were of uncertain value. There was no conclusive proof yet that viruses were filterable forms of bacteria, nor had it been established that a clinical entity was due to a single agent. Some virus maladies were induced by more than one such agent, while others appeared to be produced by the concerted action of viruses and bacteria. While it was undeniable that viruses were present in certain types of cells exhibiting inclusion bodies, there was still doubt about the nature of the small intracellular coccoid bodies. Some fowl tumours were undoubtedly caused by agents separable from cells, and this fact might have a significance in the case of human cancer, though it was by no means certain that all neoplasms arose through the activity of such agents.

Dr. J. Henderson Smith remarked that viruses in plants had essentially the same characters as those in animals, but there were differences in their effects; thus, for example, plants could not develop an active immunity. It seemed reasonable at present to adopt a provisional hypothesis that plant viruses were parasitic organisms, not necessarily bacterial or protozoal, but having special characters imposed by their small size.

Dr. S. P. Bedson gave reasons for his belief that filterable viruses were independent living entities. Although the size of these particles varied in the different viruses, each species maintained a constant order of size irrespective of the environment in which it was multiplying. Moreover, each species preserved its antigenic individuality irrespective of its environment. If a human strain of herpes was adapted to the guinea-pig and an anti-herpes serum prepared therefrom, this serum would neutralize specifically human and rabbit strains of herpes virus as well as the guinea-pig strain. Similar phenomena could be demonstrated by the complement-fixation test, and be applied equally to other viruses.

Physiological Aspects of Muscular Exercise

Professor A. V. Hill, F.R.S., critically examined the views held with regard to the physiology of muscular exercise in man. Until the end of 1926 the current theories of muscular contraction had been enunciated in terms of lactic acid, and of the energy provided by its formation from glycogen. The discovery of creatine-phosphoric acid at the beginning of 1927, and the later discovery by Lundsgaard, in 1930, that muscles treated with iodo-acetic acid would contract apparently normally, but without the production of lactic acid, involved readjustment and restatement of the conclusions based on earlier work. The present view was that the immediate chemical change in a stimulated muscle was the breakdown of creatine-phosphoric acid; this product was immediately re-formed at the expense of energy liberated by the production of lactic acid, and, later, by the oxidative restoration of this lactic acid to glycogen.

Professor J. Barcroft, F.R.S., dealt with the limits placed by altitude on physical exercise. Italian researches had shown that man could live at an atmospheric pressure of about 110 mm. Hg if he breathed oxygen, but could do little or no work. More recent investigations by himself, Douglas Kendal, and Margaria had, however, indicated that, by breathing oxygen at a pressure of 170 mm., a

man could step up 1,000 feet in an hour. This pressure was much lower than that on the top of Mount Everest; it followed that if the respiratory passages were supplied with oxygen, the feat of climbing the highest altitudes was not impossible. The problem of climbing such a mountain was one for an engineer who specialized in designing apparatus for promoting respiration in such special circumstances rather than for the mountaineer. The problems concerned included how a man could carry 30 cubic feet of oxygen; how he could rid himself of the carbonic acid if he rebreathed the oxygen; and how he could cope with such incidental difficulties as the freezing of the expired water vapour. By prosecuting investigation on these lines much less expenditure of money and lives would be entailed than was involved in the equipping of successive expeditions to the Himalayas.

Resuscitation Problems

A valuable discussion on problems of resuscitation, including asphyxia, electrocution, and drowning, was opened by Sir E. Sharpey-Schafer, F.R.S., who reviewed the circumstances which give rise to asphyxia, and the physiological conditions involved. He discussed the way in which the various methods of artificial respiration had developed, and emphasized the importance of selecting a procedure which would be simple of application and independent of apparatus. He dealt in detail with the prone pressure method, which was efficient, simple, involved no fatigue, required only one operator, and obviated any obstruction by the tongue, soft palate, or mucus. He gave instances of fatal results in cases of drowning due to turning the patient from the prone to the supine position, and commented on the danger which might ensue if the medical practitioner was uninstructed in such respects. He regretted that artificial respiration was not taught in most medical schools, and that few medical students or doctors had ever practised it. The prone pressure method had a physiological basis, when the centre in the bulb was no longer paralysed by an excess of CO_2, owing to the renewal of air in the lungs being started by the movements of the chest, it responded to each such pressure with an inspiration; in other words, each expiration caused a respiratory movement—the well-known Hering-Breuer phenomenon. In this way the method promoted the recovery of natural respiration, and might be regarded as physiological, although the direct action of the operator in the first instance was to produce expiration. Adrenaline should be given as soon as possible to promote recovery of the heart and of the arterial tone, it should preferably be injected directly into the heart in a dose of about 20 minims of the 1 in 1,000 solution, which might be repeated if necessary. In normal circumstances adrenaline was constantly being secreted into the blood by reflex stimulation of the centre in the bulb. As in the case of other bulbar centres, it was stimulated at the beginning of asphyxia, but was later paralysed by the excess of CO_2, so that adrenaline was no longer secreted, and, therefore, had to be administered. Asphyxia neonatorum, which was usually caused by obstruction of the umbilical vessels, must be treated on a different principle, because the lungs were empty of air and needed to be filled. This was accomplished, if possible, by inducing natural inspiration by stimulation of the skin, but the method failed if the respiratory centre was paralysed by an excess of CO_2. Inflation could be effected through a cannula passed into the trachea; mouth-to-mouth inflation was difficult, since air driven into the mouth was too apt to pass only into the oesophagus and stomach. If the lungs were inflated, respiration could be continued by intermittently blowing air in and allowing it to escape, or, alternatively, by pressing on the chest or abdomen, the child being in the prone position for choice; adrenaline should always be injected at once into the heart.

Professor Yandell Henderson remarked that it was not enough to resuscitate a man from drowning, asphyxia, or from any other accident, or from surgical anaesthesia, if he was to die a few days later from secondary pneumonia. He commented on the value of the inhalation of carbon dioxide as the most effective means of stimulating respiration when it was depressed or had stopped. It had also proved to be a highly useful preventive of the collapse of the lungs which led to pneumonia. Respiration was closely associated with the tone of the muscles, especially those of the thorax. Depressed breathing and a low muscular tone permitted collapse of part or the whole of a lung, and from such a collapse pneumonia developed if infection was present. The inhalation of carbon dioxide, by its action on the respiration and the muscular tonus, kept the lungs open, and prevented the development of pneumonia.

Illustrations were given by Dr. C. K. Drinker and Mr. T. J. Shaughnessy of the value of this treatment in asphyxia due to gas poisoning.

Sir Francis Shipway said that the pulmonary gaseous exchange might be interrupted by temporary paralysis of the nervous system owing to lack of oxygen or the action of anaesthetics, by paralysis of the muscles of respiration—generally secondary to paralysis of the nervous centres—and by circulatory failure; treatment had, therefore, to be based on the condition which was actually present. The pumping action of the heart was promoted by alternate expansion and contraction of the lungs, the supplying of oxygen and carbon dioxide, cardiac massage, and the injection of adrenaline. In the case of the apparently stillborn child the nervous system and heart were more resistant to the lack of oxygen than was the case in the adult. In addition to inflation measures, the application of warmth increased the excitability of the nervous system, and improved metabolism.

Professor J. A. Gunn discussed the survival time of tissues, especially of the central nervous system after stoppage of the circulation. He described in detail such resuscitation measures as massage of the heart, cardiac and respiratory stimulus, and the methods of administration and the duration and action of adrenaline. He reported a modification of Bunt's method of performing artificial respiration, which was useful in the case of the newborn child.

SECTION OF PSYCHOLOGY

The Nature of Mind

Dr. Charles S. Myers, F.R.S., president of this Section, devoted his address to a disquisition on the nature of mind, and opened with a review of the progress of the Section of Psychology since 1913, when it was separated from physiology as a Subsection; seven years later it was accorded the rank of a Section. He dealt in considerable detail with the relation of the mathematician with physics and psychology, and contrasted the past and present conceptions entertained as regards the nature and action of mind. Psychology, like mathematics, had been bereft of "reality" by the operation of mathematicians, whose particular interests lay in mathematical operations, and in numbers and figures for their own sake, and not for the sake of their physical significance. Dr. Myers then passed to discuss measurements of psychology in terms of behaviour, pointing out that the estimation of mental ability or character or quality was not achieved directly; all that could be so determined was the corresponding stimulus, or the outward response or expression by which that mental ability or character or quality was manifested. The "behaviourists" were quite correct in insisting that scientific measurement was only applicable to the behaviour of the organism. Where they were wrong was in assuming that conscious processes must necessarily be ousted from scientific psychology because measurement was excluded. Self-activity was to be regarded as the highest unitary integration of the directive mental (conscious and unconscious) activity of the organism.

After briefly considering the origin of actions and the contents of consciousness, Dr. Myers passed on to discuss multiple personalities and their redintegration, and presented an analogy based on different forms of national government. The earliest stage of consciousness was represented by a primitive monarchical government, the king being a weak, diffusely moving spirit in all its varied activities. The intermediate stage was comparable with a stronger government consisting of a cabinet with a large number of members, each busily acting in consider

able independence of his colleagues and of his chief, the prime minister. At the highest stage there might be conceived a differentiation, co-ordination, and integration as having so harmoniously co-operated as to produce a prime minister who was functionally identical with the king, and had such complete control that he regarded the more important " acts " of his hierarchy of lower-level colleagues as his own " presentations." In some such way, Dr. Myers suggested, could be dimly portrayed the evolution of the self, its increasing powers of control and devolution, its development of the function of presentation, and its ability in certain conditions to look down on what appeared to be itself, or on one or more other selves, acting and experiencing feelings and presentations. He then passed on to indicate the development of two modifications of the self—namely, feeling and presentation—and went on to deal with conscious and unconscious direction and purpose by the personality. He rebuked psychoanalysts for their failure to recognize that the nature of unconscious mental processes could never be described in terms of the human body and mind. "Psycho-morphism" in psychology was an error no less cardinal than anthropomorphism in religion. It was impossible to localize consciousness in special regions of the brain. The highest processes of learning, of comparison, and of all that underlay higher intelligent activity, had a generalized localization, and there was no warrant for supposing that there existed definite seats or centres of sensation or emotion, or for the association of such experiences.

In conclusion, Dr. Myers passed on to the relation between the directive and mechanical activities, and remarked that mental work appeared to make far greater demands on the general metabolism than it should do, according to purely physical considerations of the expenditure of mechanical energy. The psychologist's principle of the conservation of self, which corresponded with the biologist's inevitable principle of the struggle for existence, was the fundamental function of the conscious activity manifested when the physiological activities of the lower-level systems met with the highest-level activities, and became apparent as conscious " presentations." This " conservation of self " principle was as real and important as the physicist's principle of the conservation of energy.

Mental Deficiency

Dr. E. O. Lewis, who described the social aspects of mental deficiency, remarked that a complexity of conditions were involved, as shown by the many classifications of defectives, such as those into primary and secondary cases of amentia, the familial and non-familial, and the inherited and sporadic. In approaching the social aspects of the problem, however, a simpler classification into the pathological and subcultural types was more helpful. In the pathological case there was a definite organic lesion or abnormality, such as cerebral haemorrhage, hydrocephalus, or some physical defect due to toxic factors which had impeded growth. The subcultural type of defective was merely a variant of the normal, but was all-important from the point of view of the social significance of this condition, whereas the pathological group had comparatively little sociological interest. Less than half of the total number of mental defectives fell into the pathological group ; its members were mostly low-grade, and needed little more than custodial care and some simple form of training. They were fairly evenly distributed among the various social grades of the community. The subcultural defectives, on the other hand, were far more numerous, and, not infrequently, several were to be found in the same family. A large proportion of these families formed an important group in the lowest social strata of the population, giving rise to many chronic social problems. The higher the species in the biological scale, the greater was the individual variety of form, function, and behaviour. Mental deficiency of the subcultural type might be regarded as one manifestation of this variety. The endowment of innate mental characteristics varied more and more as civilization progressed, and so the problem of the subcultural group was an inevitable concomitant of the advance of civilization. Economic and social factors tended to segregate the subnormal members of a social group in certain districts, where they became a financial burden upon their families or upon public funds. The assimilation of this group, and of the still larger contiguous group—" the subnormal tenth "—into the general life of the community constituted one of the most difficult problems that Western civilization had to solve.

Professor F. A. E. Crew, dealing with the genetic background of mental defect, said that in the case of the human subject the geneticist did not collect his own data, but used the clinical records collected by those unskilled in psychology, and who were too prone to accept anecdote in place of evidence. There was so much variety in diagnosis and in interpretation that it was impossible to determine whether mental defect, as defined, could be the expression of different genetic forces ; but it was certain that there was a genetic background of mental defect. Mental deficiency could be eradicated by breeding, if parentage was denied to all who carried the hereditary ingredients ; but the success of any attempt to control the spread of these among a population would be determined largely by the nature and the number of the genetic factors involved.

Drs. R. G. Gordon and R. N. Norman reported psychological experiments on different types of mental defectives, which had been conducted in order to discover the distribution and nature of various functions. Two series of patients were investigated—namely, 100 adult girls with an intelligence quotient of over 40 per cent., and 109 boys of the idiot and imbecile class. Head's aphasic tests were tried, and those concerned with verbal and language manipulation proved much easier for the defective than did those concerned with spatial discrimination and manipulation. Rorschach's blot tests were applied to the same two series of patients to test the nature of visual imagery, the observation of colour, and the tendency to descriptiveness. Imagery was found in all cases to be restricted in scope, and confined to concrete objects within the limited experience of the defective. Colour was noticed by a minority of the subjects, and descriptiveness was more characteristic of the responses of the higher grade of children. Thorndike's puzzle box test was used to determine the possibility of the patients grasping a spatial and mechanical problem as a whole, of learning by experience, and of applying the solution of simpler puzzles to help in solving more complex problems. The last two capacities were well developed in both groups, so much so in the higher-grade subjects as to make the serial tests valueless for them. The lower-grade subjects showed a varying ability to solve the more complex puzzles in the light of simpler ones. Yerkes's discrimination tests were modified to test the power of retaining the image of a spatial configuration, but proved useless for the higher-grade cases. In the lower-grade patients interesting results were obtained, but they only indicated so far how this method might be usefully applied in a more elaborate research. All these experiments revealed a general but by no means exact correlation with intelligence as measured by the Binet and Porteus tests.

Dr. F. C. Shrubsall compared the frequency of the types found in the course of a statutory ascertainment with those defined by Dr. E. O. Lewis in his special investigation. Among other conclusions reached was the discovery that mental age was only one of the factors in deciding on suitability for a special school. The intelligence quotients of the ineducable showed no relation to the type of defect.

SECTION OF CHEMISTRY

The Vitamins

Sir Frederick Gowland Hopkins, P.R.S., opened a discussion on vitamins by pointing out that certain definite knowledge was now available about the constitution of these substances ; discussion of food factors by the Chemistry Section was thus now fully justified. As the result of oxygenating certain animal fats it had been shown that vitamin A was more easily oxidized than vitamin D. All doubts as to the individuality of these two vitamins had disappeared with the acquirement of new chemical facts. Sir Frederick Hopkins outlined the characteristic symptoms due to deficiency of each

substance, and mentioned the recent meeting of an international committee in London, when it was made clear that there was now available a technique in respect of biological standards; this would certainly lead to results of a more practically useful character as regards the administration of vitamins. The next task of the physiologist was to discover how the very potent influence of these substances was exercised in the human body, and how such minute amounts could produce such profound effects. When the synthetic chemist knew all that was to be known about their constitution it was possible that he might improve upon nature, and obtain from his synthetic products still more startling results than those which had accrued from the natural preparations.

The chemical constitution of vitamins was outlined by Professor P. KARRER, who remarked that, although vitamin A from cod-liver oil was not identical with carotene, yet active vitamin A preparations when ozonized produced geronic acid, just as carotene did. The vitamin A of cod-liver oil must therefore contain in its molecule the same carbon ring as carotene, and in that sense could be regarded as a derivative of it.

In close connexion with Professor Karrer's contribution, Professor H. VON EULER summarized recent investigations into the biological and biochemical effects of the carotenes, some carotene derivatives, and other growth-promoting factors. He said that the current view was that only one vitamin A was present and active in the animal body, but the discovery of the heterogeneous nature of carotene seemed to support the suggestion that there were several fat-soluble factors of the vitamin A type.

Dr. T. MOORE, discussing steps in the concentration of this vitamin, stated that all natural mammalian-liver oils were richer sources of it than was cod-liver oil, although this superiority might be set off against the much smaller amount of oil present per unit of liver. The mammal offered an additional advantage in being amenable to artificial feeding before treatment of the liver, by which means the vitamin A content might be raised very high. He cited experimental results which shed further light on the changes which must occur in carotene so converted to vitamin A by the animal. Such a conversion was accompanied by at least a tenfold increase in colour value, but it did not seem necessary to assume that the spectroscopically different colour units given by carotene and vitamin A must bear the same relation to biological activity. So far as could be judged from a limited number of tests the best concentrates were not more than two or three times as active as crystalline carotene.

The chemistry of vitamin B and related problems was discussed by Professor B. C. P. JANSEN, who described the method adopted by himself and Dr. Donath in isolating the anti-neuritic B, vitamin. Mr. R. B. BOURDILLON announced that attempts to isolate crystalline vitamin D from the resinous mixture obtained from the ultra-violet irradiation of ergosterol had now been partially successful in three different countries—England, Germany, and Holland. He suggested that the three different products might be mixtures in different proportions of two nearly isomorphic anti-rachitic compounds: one showing a high dextro-rotation and considerable stability, the other being less stable and presenting laevo-rotation or low dextro-rotation.

HEALTH WORK OF THE LEAGUE

[FROM OUR CORRESPONDENT IN GENEVA]

The work of the Health Organization of the League of Nations has produced the usual crop of appreciative speeches in the present Assembly, but this year the desire for economy has silenced virtually all proposals for new enterprises. The only new work to be undertaken consists of medical help to be given to China with the object of averting epidemics which might be expected to follow the recent floods. Even here no large expenditure is contemplated, but only the loan of the services of experts and the grant of medical stores.

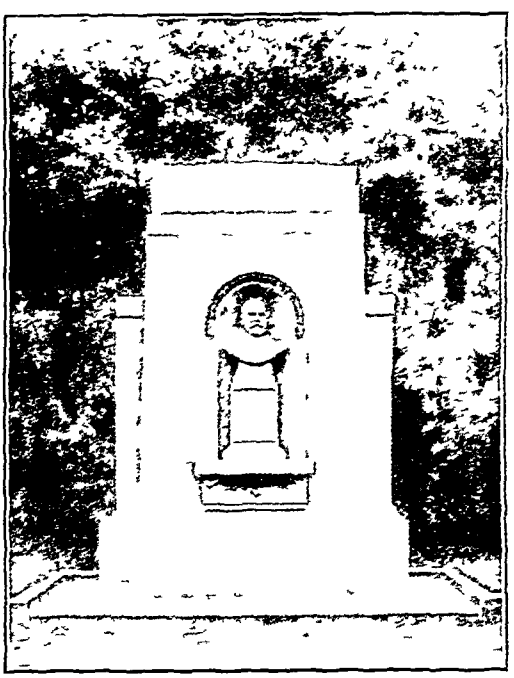
The health work of the League was reported on by Dr. Fierlinger, delegate of Czechoslovakia, who stated that during the past year the Health Organization had developed one of its most important tasks—that of giving assistance to Governments who asked for it with regard to methods to be employed to solve general and special administrative and medical problems in the sphere of public health. He mentioned the liaison which has been established with the Ministry of Public Health and Physical Education in his own country, also the medical assistance given by the League to Bulgaria, the inquiry into the causes and means of prevention of infant mortality in Rumania, the mission sent to Liberia to advise on health matters, the programme undertaken for the reorganization of the Bolivian Health Service, the study which has taken place in various South American countries on the measures for combating the perils which threaten early infancy, and the conference recently held at Montevideo on serological methods for the detection of syphilis. A great deal of special work has been undertaken in China, a country which is now being visited by Dr. Rajchman, the director of the Health Organization. A central health station is being organized at Nanking to form the nucleus of a national health service, and the first national hospital, also at Nanking, is already working at full pressure. The Chinese national quarantine service began its task several months ago in a number of localities. A standard programme of instruction has been drawn up for Chinese schools of medicine. An effective organization against cholera is being set up in the Shanghai zone. Most recent of all is the urgent work which has been set on foot, through the health services of neighbouring countries, to prevent the spread of epidemics from China, in view of the flood disaster in that country, resulting in starving communities, crop failure, refugee camps, and vast areas under stagnant water. So much for the special work of the year. Turning to the more or less permanent tasks of the Health Organization, Dr. Fierlinger referred to the Eastern Bureau at Singapore, which, he said, was steadily increasing in usefulness as a result of technical improvements in the transmission of notifications of infectious disease.

The collective study tours known as interchanges are being continued. A tour of this kind has lately been in progress in Great Britain for the study of questions concerning milk supply and disinfection of ships. The French Government has offered to establish in Paris an international school for advanced health studies, with the object of continuing and centralizing, through a permanent institution available for all nations, the work already done in this field by periodical meetings of directors of various schools of hygiene, by the system of interchanges, and by a grant of scholarships. The Permanent Commission on Standards has adopted several new international standards for serological products. Inquiries made by the Malaria Commission have led to the definition of a standard product of the total alkaloids of cinchona (the "totaquina"), which has the same effect as quinine, and is likely to meet the necessity for an increase in the supply of the active product, and probably reduce the cost of treatment.

Finally, Dr. Fierlinger spoke of the European Conference on Rural Hygiene. This conference, in which the Health Organization, the International Labour Office, and the International Institute of Agriculture participated, was attended by eighty-six delegates and experts from twenty-five European countries. That its influence spread beyond

Europe was proved by two other speeches in the Assembly from delegates of Canada and of Australia—both women, and the Australian a woman doctor—who said that the work of the European conference had been fruitful of suggestions which were capable of adaptation to their own sparsely populated territories

Lord Astor, one of the principal delegates of Great Britain to the Assembly, referred to the important work undertaken by the Permanent Commission on Standards He said that this work did not perhaps appeal much to the popular imagination, and yet it was of the greatest utility There was always a risk said Lord Astor, that in these days of economy an uninstructed public opinion would demand the abandonment of some form of beneficial activity not understood by the man in the street The objects of the commission are to standardize modern products in medicine, such as insulin, antitoxins, and the like, so as to ensure that in different countries, as far as possible, the same methods of testing and dosage, and the same terminology, are employed



The discussion on health matters in the Assembly covered a wide range and included an interesting speech from another medical delegate, Dr Chodzko of Poland, who gave a rather startling account of how the doctrines of Malthus as he said, are spreading even in the most secluded parts of Europe The Slavs are no exception, and according to this authority, are practising on a widespread scale the artificial limitation of births

JAMES MACKENZIE MEMORIAL

CEREMONY AT BURNLEY

In October, 1929, Lord Moynihan President of the Royal College of Surgeons of England opening the new radium clinic at the Burnley Victoria Hospital drew public attention to the fact that nowhere in Burnley was there any outward record of the long and notable association of the late Sir James Mackenzie with that town The publicity given to Lord Moynihan's observation aroused much interest locally, and very many old friends and colleagues of Sir James expressed a desire to assist in remedying an omission which, they felt, reflected unfavourably on Burnley

The Mayor (Alderman H R Nuttall, J P) thereupon convened a meeting of those likely to be interested, at which it was decided to open a public subscription list As a result of the appeal that followed, sufficient funds were speedily obtained to enable consideration to be given to the form of the memorial The committee set up by the subscribers after giving much thought to the matter, came to the conclusion that the memorial should take two forms — namely, a plaque on the wall of the house in Burnley, No 68 Bank Parade, in which James Mackenzie resided for many years, and a bust in a suitably chosen position

MACKENZIE MEMORIAL AT BURNLEY

On Saturday last, September 26th the two memorials were unveiled at a public ceremony—the plaque by James Mackenzie's brother, Lord Amulree, G B E, K C, Secretary of State for Air, and the bust by Lord Moynihan The plaque bears the following inscription

Sir James Mackenzie M D, LL D F R S, F R C P, 1853 1925 Who achieved fame by his researches in connexion with diseases of the heart, was from 1879 to 1907 a general practitioner in Burnley and lived in this house

The Burnley Town Council gave permission for the bust to be placed in Thompson Park, and the site chosen, the easterly side of the Rose Garden, gives a good background to the monument and is particularly appropriate It is within a very short distance of, and can be seen from, No 68 Bank Parade

The bust has been modelled by Mr L F Roslyn, R B S, of South Kensington It is of cast bronze and has been placed in the niche of a monument eight feet wide by twelve feet high built of polished Darley Dale masonry provided by the town council

LORD MOYNIHAN'S ADDRESS

The following address was delivered by Lord Moynihan when unveiling the bust in the Rose Garden at Thompson Park

This is a day of remembrance! To-day we commemorate the life, and pay tribute to the service, of one who was Burnley's most distinguished citizen, perhaps the greatest general practitioner we have ever produced, and who was certainly possessed of the most original and acute mind of any physician who has practised in this country during the last fifty years

"Sir James Mackenzie's mind was not so much acquisitive as observant and creative As with Hippocrates, whom we call the Father of Medicine, his eye saw things which escaped the observation of others his mind retained not only the broad truths, but even the minute details of things once seen, and in due time the facts observed were marshalled, correlated, contrasted compared until a great general truth emerged The intellectual road was often long and rough the path beset with problems of bewildering complexity, he was perpetually halting to ask questions and an answer when found showed, as always in science the need for new and still more difficult inquiry Yet in the end we must confess that though he never gained intellectual contentment and repose he rarely failed to accomplish something that steadily advanced the science of medicine, and brought a real help to those who suffered Indeed, I always felt that the virtue which was his main incentive

was compassion. Mackenzie loved his fellow men; he was consumed by a longing to help them, to save them from suffering, to strengthen them for their daily task, to sustain their faltering courage in times of danger and distress, to rescue them from death. These desires were the mainspring of his untiring labours. Was he not therefore most justly called the 'Beloved physician'?

"This tablet perpetuates the view that Mackenzie's greatest work was concerned with disease of the heart. A philosopher might, however, claim that his method of work was greater even than its results. It is indisputable that he created new knowledge, vast in quantity, of highest value, and most relevant in application to maladies of the heart. Yet to the science of medicine he contributed something of at least an equal importance: he vindicated the Hippocratic method in medicine, the method of accurate clinical observation leading to the power of classification, and of wide generalization. He was indeed the great observer, the keen, thoughtful eye-witness of events which he submitted to an almost vexatious scrutiny, that he might satisfy himself of their truth and of their contesseration. I think he rather disdained the academic scholar, the learned collector of other men's opinions, the bookworm who knew old and new authorities alike. Once I reminded him of the story of Jesse Foot, the enemy of immortal John Hunter whom he reviled for his ignorance of the Latin tongue. 'Jesse Foot rebukes me that I do not know the dead languages; but I could show him that on the dead body that he never knew in any language dead or living.' So I pointed out to Mackenzie that he might himself say to those learned only in the classic literature of medicine, 'I can show you that on the living heart that you will never find in books, ancient or modern.' His invention of the polygraph, first made in Padiham, a feat acclaimed throughout the world, which enabled him to read the heart's actions as in a book, was only an incident in his unwearying search for truth.

"When Mackenzie left Burnley he was already regarded throughout the world as the most eminent of English physicians. He faced the venture of his journey to London with equanimity. 'If I get consulting work, I shall do it; if I don't, well, mon, I shall just play gowf,' he said to me, in rugged Scottish accent. London received him as silently and at first almost as indifferently as years before it had received Lister. But little by little London was conquered, and to his consternation the 'Mackenzie school,' not entirely to his liking, was founded. Many of his disciples failed to grasp the real significance and the philosophical basis of Mackenzie's work. So after years of work of highest quality, both literary and professional, after expressing his longing to get back to general practice, he retired to St. Andrews and established the Institute there. In the end he died in London of the disease he had studied so carefully, angina pectoris, adding one more to the examples of those who succumb to a disease which had been their main interest during their professional lives.

"Mackenzie was indeed the beloved physician. He was the sanest and most powerful influence in English medicine for a whole generation; he added knowledge of incalculable value to its science; he renewed and strengthened our faith in the ancient method of Hippocrates; he held aloft the standard of our profession, and caused it to be honoured throughout the world. He made a multitude of friends wherever he went; he stirred hope in many hearts that were afraid, and gave comfort to those who suffered. Great men praised him for his knowledge, his wisdom; all men loved him for his tenderness, his gentleness, his power that gave them strength, his courage that inspired them, his skill that saved them. His presence was a benefaction; his memory will forever be an inspiration."

After the unveiling Lord Amulree moved a vote of thanks to Lord Moynihan, and speeches by the Right Hon. Arthur Henderson and Professor John Hay, M.D., of Liverpool, brought the ceremony to an end.

Scotland

Scottish Mental Hospitals Board

The report of the Scottish Mental Hospitals Pathological Scheme for 1930 has just been issued. It is pointed out that the researches are of a scope and on a scale which would go beyond the resources of the individual hospitals, and are secured by co-operation between the various Scottish mental hospitals. The Board considers that the amount of research work on neuropathology which has been carried out by Dr. F. E. Reynolds and his fellow-workers in the last seven years has furnished ample justification for the continuance of the laboratory. A monograph containing important joint researches by Dr. Logan Turner and Dr. Reynolds on pyogenic intracranial diseases has been prepared, and is ready for publication. The revenue for the year amounted to £2,204, and the expenditure to £1,272. The Medical Research Council contributed a grant of £200 to the fund for the current year. In addition to research work, reports are made on specimens sent by contributing hospitals; some two hundred specimens were dealt with during the past year.

Edinburgh Practitioners and the Capitation Fee

A well-attended meeting of practitioners on the Edinburgh panel was held in Edinburgh on September 22nd, when it was agreed to accept the proposed reduction of one shilling in the capitation fee. The meeting, however, was of the opinion that more attention should have been paid to the statement of certain principles which may have to be taken into account in future negotiations. These are that the sacrifices made by practitioners in 1922 and in 1924 in aid of national economy, which represented a reduction of two shillings in the capitation fee, should have been emphasized; that the present capitation fee is not sufficiently above the pre-war rate to be commensurate with the cost of living; and that a period should have been defined after which the amount of the capitation fee would be considered.

Open-air School at Edinburgh

A new building of the open-air type, Prestonfield Primary School, situated in Peffermill Road, Edinburgh, was opened on September 22nd by Councillor P. H. Allan, chairman of the Edinburgh Corporation Education Committee. The school has been built to meet the requirements of the neighbouring housing scheme at Prestonfield, where about seven hundred houses have been erected within recent years. The classrooms are built on one floor only, and have a pleasant garden in the centre. In fine weather the sides of the classrooms, which are provided with glass doors throughout their full length, can be completely opened, so that the pupils can enjoy the full benefit of the open air. The school is the first in Scotland to have an "under-floor" heating system. There are fourteen classrooms, with accommodation for seven hundred pupils, in addition to a sewing room, a large hall or gymnasium, and the usual arrangements for staff, medical inspection, and stores. At the opening ceremony Councillor Allan remarked that the Education Committee of Edinburgh had been guided by the fact that "more men fail from want of energy than from want of ability." Although the vagaries of climate might often prevent the full use of the facilities provided it would usually be possible to take at least partial advantage of them with resulting benefit to health. The school was of the nature of an experiment, and its success depended, to a large extent, on the teachers.

Economies in Medical Services, Fife

A committee of the Fife County Council has made various recommendations for the restriction of expenses in connexion with medical services in this area. Certain changes in the county hospitals, including the closing of St Andrews Poor Hospital are expected to effect a saving of £2,500, and an amalgamation of areas would cut down the number of parish medical officers, with resulting saving in salaries. The Public Health Committee is requested to revise the scheme for nurses and health visitors, with a view to reducing the number of nurses. The committee also recommends that the scheme for supplying milk to school children should meantime be postponed, as the medical officer of health is satisfied that the school children are well nourished. The reduction of the ordinary scale of poor relief by 10 per cent. and of the clothing allowance by 20 per cent., is advocated among other economies, the estimated saving being £9,000. The committee drew attention to the growing costs incurred at the Springfield Asylum for the Insane, and proposed that the expenditure for this district asylum should be reduced by £2,000.

Ayr Hospital Co-operation

At a meeting on September 14th the Town Council of Ayr considered a report from the Department of Health concerning the hospitals in Ayrshire including the proposals advanced for the utilization of the accommodation available. It is suggested that it would be economical and ultimately in the best interests of the county and the various burghs concerned if Kirklandside Hospital, Kilmarnock, were developed by co-operation between the town councils of Ayr and Kilmarnock in such a way that it would eventually become the central council hospital of the district. It would then supplement the various voluntary hospitals, and would provide for infectious diseases and abnormal obstetrical cases besides supplying generally, extra beds for medical and surgical cases. At present the authorities of Ayr burgh, Ayr county, and Kilmarnock burgh co-operate to a certain extent, and it is considered that this definite step in organization should offer little difficulty.

England and Wales

Sir Robert Bolam

The House Committee of the Royal Infirmary, Newcastle-on-Tyne, in its last quarterly report, announces with much regret the retirement from the honorary medical and surgical staff of Sir Robert Bolam, O.B.E., M.D., LL.D., F.R.C.P., honorary physician in charge of the Skin Department, on having reached the statutory age limit. Sir Robert Bolam has been associated with the work of the Infirmary for a period of thirty-two years, and the committee are deeply sensible of the loss which his retirement entails. They wish to place on record their appreciation of the valuable services he has rendered and their recognition of the distinguished position held by him in the profession. They have also agreed that an illuminated address be presented to him. Further, the committee have unanimously agreed upon a recommendation which appears on the agenda, to appoint Sir Robert Bolam an honorary consulting physician to the Skin Department.

British Red Cross Society

In a foreword to the report of the British Red Cross Society for 1930 Sir Arthur Stanley comments on the encouraging progress that is being made at the Central Clinic for the Treatment of Rheumatism in Peto Place, Regent's Park. Since the clinic began to admit patients in March last year, the average weekly attendance has risen to well over a thousand and it is estimated that about 70 per cent. of the male patients, and 80 per cent. of the female, have definitely benefited. During this experimental period sufficient experience has been gained to determine the probable cost of treatment per attendance, and a revised list of fees is being prepared. The hope is expressed that in time the clinic will be more or less self-supporting. At present the active medical staff consists of five visiting physicians, with their clinical assistants, a specialist staff, a medical registrar, a matron, and the treatment staff. The social service department is directed by a lady almoner. It will be recollected that the clinic admits adult walking patients only, and that all patients, without exception, are required to have a recommendation signed by a doctor. The clinic is open from 8.30 a.m. to 9.30 p.m. daily, except Sundays. A full report of its work is published separately, and may be obtained on application. During the year requests for blood transfusion numbered 1,627—the highest figure so far recorded. This service was utilized by 115 hospitals apart from nursing homes and private cases. A point is made of the number of middle-aged and elderly persons who are enrolling as donors, owing apparently, to the reports of younger relatives of the feeling of fitness that follows a transfusion. While expressing satisfaction with this department of its activities, the society resents that the voluntary nature of the service is being exploited for the benefit of more or less well-to-do patients. Out of 156 private cases served during the year, less than fifty patients made any donation. Increases in membership are recorded in the voluntary aid detachments now numbering 735, in the British Red Cross detachments, and in the Junior Red Cross, in which 17,838 boys and girls have been enrolled. During 1930 notewothy progress was made overseas, branches of the society having been established in Kenya and in Southern Rhodesia. In this country the reports of the county branches, which are incorporated in the report, show steady development.

Medical Aspects of the Gas Industry

During the annual conference of the British Commercial Gas Association in Exeter from September 28th to 30th, special attention was paid to the part that might be played by coal gas in promoting the public health, and as a source of radiant energy for the treatment of disease. Dr. Meredith Davies, county medical officer of health for Devon, emphasized the importance of gas as a smokeless fuel for private houses as well as for factories. He said it was clean, efficient, and reliable in use, and eliminated the drudgery and fatigue involved in antiquated methods of heating and cooking. It satisfied modern standards of hygiene, comfort, and ventilation in room heating, provided hot water, and also was utilized in the cheapest automatic refrigerator on the market. It facilitated the use of coal by the population in such a way as to make the conditions of living as healthy as possible. In an ideal house installation there would be an automatically controlled central heating apparatus to keep the air temperature correct all over the building, and some source of radiant heat associated with a form of ventilating system in every room occupied for any length of time. In the ordinary living room however in the temperate climate of this country, the source of radiant heat would generally be sufficient to maintain an equable air temperature. Dr. Meredith Davies commended panel heating, mentioning that panel heaters in the ceiling delivered the highest percentage of radiant heat, though in the wall emanated about 60 per cent. of their heat in the radiant form when running at about 100° F. Owing to the amount of reflection from the walls and furniture the heating provided by ceiling panel mechanisms was remarkably even,

the air temperature was practically constant, except for a few inches from the ceiling. Gas light was less tiring to the eyes than any other artificial illuminant; the fumes which had been regarded as an objection in the past consisted only of carbon dioxide and water vapour. Sir Leonard Hill remarked that gas provided the long ultra-violet rays which were considered by the Finsen Institute to have a curable effect in cases of surgical tuberculosis. It also gave off the visible and infra-red rays which were of importance in flushing parts of the body with blood, warming up damaged tissues, and promoting resistance to infection. These activities were of special significance in regard to the treatment of rheumatic diseases. Sir Leonard described certain types of gas lamps with the aid of which cases of chronic rheumatism had been treated, with resulting alleviation of the pain and the improvement of stiff and swelling joints. They could be kept in action for five hours at a cost of 1d., and could be used safely in the home or the doctor's consulting room.

India

The Incidence of Diphtheria

In an appendix to the report of the King Institute of Preventive Medicine, Guindy, for the year ending September 30th, 1930, it is remarked that an outbreak of diphtheria investigated by the Institute suggests that, contrary to general opinion, such occurrences are not infrequent in India. A patient with conjunctivitis and sore throat developed later paralytic symptoms. The throat swab was found to be positive, and contact cases were detected; further cases of diphtheria ensued, and a bacteriological unit was sent to the locality to make an extended investigation. Complete proof of the nature of the epidemic was forthcoming, both bacteriologically and in the immediate response of some patients to antitoxin. Infection was traced to personal contact in the out-patient department of a hospital. No definite diphtherial membrane was discovered in any instance, and it was noteworthy that in spite of the lack of isolation and proper treatment, the disease did not spread rapidly. It is probable that the diphtherial strains were of low virulence; possibly the prevailing dry and hot atmospheric conditions contributed to the insignificance of the outbreak. Attention is drawn in the report to the lack of satisfactory purification of water in several places, in spite of instructions previously issued. Lieut.-Colonel H. H. King, director of the Institute, mentions that considerable improvements to the main buildings are being carried out.

Madras Hospital for Women and Children

The publication of the annual clinical report for 1929 of the Government Hospital for Women and Children at Egmore, near Madras, has been delayed owing to the reorganization of the report on the lines of similar institutions in Great Britain. The result is a volume consisting almost entirely of gynaecological and obstetrical reports, which will be of service to those who wish to compare conditions in India with those elsewhere. During the year under review certain important changes were made in the internal arrangements of the hospital. The admission department was separated from the main delivery ward, in which one large room has been equipped for all operative deliveries short of Caesarean section. This has greatly facilitated the work, since emergency obstetrical operations can now be conducted without delay, no special preparations having to be made; strict aseptic and antiseptic conditions are enforced. In the admission department, now in another part of the hospital, arrangements have been made to obviate the transmission of sepsis from cases already infected. An attempt is also to be made to diminish chances of cross-infection; it is hoped to provide separate delivery cubicles. An ante-natal department has been inaugurated in a separate block, and venereal cases are now treated apart from the general out-patients. It is hoped to obtain an ante-natal block and children's department away from the main blocks of the hospital, and instruction in mothercraft is already being given by experts. In December, 1929, a research department was opened. Work is being carried out on the anaemias and toxaemias of pregnancy and on the causation of stillbirth. As fuller facilities are obtained, it is proposed to make further investigations into the tropical diseases which complicate pregnancy in India. This research work is being conducted in close co-operation with the director of the King Institute, and with the professors of pathology and biochemistry. Clinical meetings of the hospital staff are held monthly, each member being responsible for reporting the work of his particular section, and for the presentation of any specially interesting case. Post-graduate instruction continues to be given, students coming from all parts of India, Burma, the Straits Settlements, and Ceylon. The extent of the clinical material available is indicated by the fact that during the year under review 7,084 women and 661 children were admitted for treatment. Lieut.-Colonel C. A. F. Hingston, superintendent of the hospital, states that the chief methods of treating eclampsia were the control of the blood pressure by the administration of veratrone; the injection of morphine or omnopon to prevent the recurrence of fits; intestinal lavage to relieve intestinal toxaemia; iced enemas, and other measures to control hyperpyrexia; and general precautions against pulmonary complications and respiratory or cardiac failure. Emphasis is laid upon starvation and elimination; in most cases, delivery was either natural or aided by forceps in the second stage.

Accommodation in Mental Hospitals

The provision of increased accommodation in mental hospitals in various parts of India is becoming a serious question, especially since few steps can be taken owing to general lack of funds. In his report for 1930 of the mental hospitals in the Madras Presidency, Major-General C. A. Sprawson, I.M.S., Surgeon-General with the Government of Madras, points out that while the average population of the largest of the three hospitals in Madras, Waltair, and Calicut respectively, was over 1,000, it has a normal accommodation for less than three-quarters of that number. Moreover, the population is tending to increase yearly, and although schemes are contemplated for further building, it is already obvious that the numbers of mentally afflicted patients are sufficient to fill the three hospitals, even after their anticipated enlargement. It is also urged that the time has come for establishing a home for mentally defective children in connexion with the Madras institution, there being at present more than thirty such children below the age of 16 in the hospital, and many more outside it. A start might be made, it is suggested, by providing a day school for the high-grade mental defectives, and a home for idiots and imbeciles. A medical officer is already available for this special work. It is thought that a fourth mental hospital in the southern part of the Presidency will be urgently needed in the near future. In the Indian Mental Hospital at Ranchi the total number of beds is less by 162 than the combined total of the three hospitals which it replaced in September, 1925. The overcrowding of male patients in this institution has constituted a very difficult administrative problem, as nearly half of them are of the criminal type. A scheme of expansion is being designed

which will raise the accommodation from the present 1,286 to 1,600, the largest number with which a single institution under one administrative head can conveniently cope. Some success has attended an effort to place under the care of friends and relatives the incurable, but harmless, patients, who formed such a large proportion of the inmates when the institution was first opened. Curative measures are seriously hampered by the restriction of space, and it has not yet been possible to construct for paying patients wards which could be completely self-supporting. In the Provincial Mental Hospital at Tezpur in Assam, however, considerable improvement has followed the reconstruction of the hospital, permitting the reduction of overcrowding. It was only possible previously to accommodate the most serious chronic cases, a selection from the worst of those which had been detained in jail until room could be found for them, the recovery rate was naturally affected adversely. Since enlargement of the institution the patients have gained obviously in general health, but it is mentioned in the annual report for 1930 that some time must necessarily elapse before it will be possible to clear up the aftermath of diseases, such as dysentery and tuberculosis, due to the previous overcrowding.

Correspondence

BREECH PRESENTATION

SIR,—In the correspondence on breech presentation in your issue of September 19th three important points are raised:

1. *Should midwives be allowed to take sole charge of breech cases?*—According to the rule of the Central Midwives Board they must report breech presentation in the primiparæ, the rule should certainly be extended to the multiparæ. It is not always certain if a breech delivery will be easy, and a qualified doctor should have the responsibility. In addition, if a diagnosis of breech is made when a shoulder is presenting, disaster will occur and has occurred. Let the Central Midwives Board authorize alter the rule.

2. *The size of the parents' heads.*—I always teach my students to ascertain, when possible, the size of the husband's hat. It is of great assistance sometimes in determining treatment.

3. *The question of version.*—After a version, carefully and gently done, the fœtal heart has stopped. This is due either to interference with the placental circulation or entanglement of the cord. Version therefore, is not without its danger.—I am, etc.,

Dublin, Sept. 28th. BRUNET SOLOMONS,
Master Rotunda Hospital.

THE TREATMENT OF CHRONIC OSTEOMYELITIS

SIR,—In your issue of September 19th you devote an editorial note to the treatment of osteomyelitis by maggots, and mention also Dr. Winnett Orr's method. Both of these have always struck me as thoroughly unsurgical and somewhat offensive method of treatment. It must surely be very disagreeable to the patient to have his wound attacked by animal scavengers, and those who have tried Winnett Orr's treatment bear witness to the fact that the fetor of the discharge is such as to make it practically impossible to nurse other patients in the same ward.

You suggest that osteomyelitis is more common in the United States than in this country, but surely no hero have surgeons been faced with a greater problem in the treatment of this condition than that presented to them at the end of the war. The vast majority of the large number of severe and complicated cases of chronic osteomyelitis which resulted from war injuries were satisfactorily dealt with by ordinary surgical measures, and the failure to carry on the work in the treatment of the much smaller number of civilian cases can only be due either to lack of appreciation on the part of the surgeon of the principles upon which a radical operation should be carried out, or else to a lack of boldness in carrying the operation through in an adequate manner.

The radical operation was originally described by Professor Broca, whose book on the after-effects of wounds of the bones and joints was translated into English in 1918, and gave a very thorough account of the method of radical treatment. A description of the principles of Broca's method was published by me in *The After-Treatment of Wounds and Injuries*, and in Sir Robert Jones' *Orthopædic Treatment of Injuries*. These principles are briefly (1) that all tracks and sinuses in the bone must be well opened up, leaving no escape from it by removing all granulation tissue, and, as far as possible, all sclerosed bone; (2) that no cavity with raised walls must be left into which soft parts cannot fall. A cavity which cannot be obliterated interferes with healing. When necessary, muscle must be loosened, or even a muscular flap cut in order to carry out the principle. When such a radical operation has been properly performed many of the wounds can be sutured immediately with a small drain. But even when the surgeon feels himself not confident to suture the wound he can practically always do it and leave it to granulate, or carry out a secondary suture at the end of ten to fourteen days.

The radical treatment of chronic osteomyelitis is one of the boons of war surgery, which has been too little appreciated since, and which it is to be feared may be completely forgotten.—I am, etc.,

London, W.1, Sept. 24th. R. C. LEWIN.

plete ignorance on our part of the etiology. My objection to the use of the label "serous meningitis" in these cases is that on account of its traditional value it may lead the physician to believe that he has made a complete diagnosis and so allay the spirit of inquiry. Looked at from this point of view serous meningitis is not a diagnosis but a luxury.—I am, etc.,

C. P. Symonds.

London, W.1, Sept. 26th.

SPINAL ANAESTHESIA

Sir,—I was asked by the secretary of the Section of Anaesthetics to take part in the discussion of Dr. Howard Jones's paper at Eastbourne, but was unfortunately prevented from being there. His paper has now appeared in the *Journal* of September 12th, and I venture to repair the omission. With many of his general conclusions—for example, that for the strong muscular man needing a high laparotomy spinal analgesia is strongly indicated—all who have had extensive experience will agree. It is with his remarks under the sections headed "Spinocain and durocaine" and "Respiratory embarrassment and collapse" that I feel he is an unreliable guide.

He persists in the idea that spinocain and durocaine act as if they were heavier than cerebro-spinal fluid, when in fact they are lighter. His explanation of this curious phenomenon is that the alcohol content, which makes them lighter, is absorbed as soon as it enters the cerebro-spinal fluid, leaving the remainder (novocain, gliadine, and normal saline) as the heavier constituent. This is ingenious, but not in accordance with the facts. Pitkin particularly warns all users of spinocain not to inject in the sitting-up position, because the solution rises too rapidly. An extensive experience of both the lateral and upright positions leaves no doubt whatever that a higher anaesthesia is obtained in the sitting-up position than in the lateral. I think that all who have had much experience with these solutions would confirm this observation.

He says: "The 'air bubble in a spirit level' arrangement is possible only between two media which are not miscible." Possibly as a general statement of a physical phenomenon that may be true. In the matter in hand it is misleading. Durocaine is miscible with cerebro-spinal fluid, but it takes a long time to become completely mixed. If 0.5 c.cm. durocaine is dropped on to the surface of 1 c.cm. of cerebro-spinal fluid at the bottom of a test tube, each drop falls a certain depth, and then gradually comes to the surface. The whole of the 0.5 c.cm. durocaine sits on the surface of the cerebro-spinal fluid, the two fluids being quite distinct and separated by a less translucent layer at their junction. Gradually the cloudy juncture-layer puts forth arms into the subjacent cerebro-spinal fluid, and in the course of one to two hours the mixture appears to have become a slightly opalescent homogeneous mixture.

Seeing that the physical facts are in harmony with the clinical findings, it seems unnecessary to have recourse to wholly imaginary physical phenomena which would explain none of the observed facts. It is true that at a later stage, when the analgesia is as high as is desired, the Trendelenburg position is a "constant feature in the ritual": certainly, to prevent the anaesthesia going higher. Moreover, the Trendelenburg position is, or should be, a constant feature in the ritual of all spinal anaesthesias that paralyse vaso-constrictors. Again, Dr. Howard Jones says: "The danger in intrathecal administration is not a vasomotor effect from a regional block of the thoracic and lumbar roots . . . but from blood absorption and paralysis of the vasomotor centre, leading in some cases with excessive dosage to severe collapse to a pulseless state." Dr. Howard Jones makes this statement, but does not support it by any facts. If he is referring to percaine, of course his clinical experience with that drug would be valuable evidence almost amounting to proof that percaine paralyses the vasomotor centre by blood absorption. As regards novocain the facts are quite otherwise. It has absolutely no paralytic effect on the vasomotor centre whatever. The proof of this will appear in a paper now being prepared for publication, in which it is shown that the injection of novocain into the cisterna magna has no such effect. If the direct application of novocain to the centre itself has no paralysing effect on it, it is idle to suppose that any dose absorbed from the lumbar theca into the blood stream could affect it in this way.

What are the facts? The largest dose of novocain (as spinocain and durocaine) that I ever use is 0.3 gram. The minimum lethal dose of novocain intravenously is 0.04 gram per kilo; for a man weighing 10 st., or 70 kilos, the minimum lethal dose would be 2.8 grams—that is, more than nine times the maximum dose ever used. Moreover, the minimum lethal dose kills by paralysis of the respiratory centre; there is no evidence that the vasomotor centre is even weakened.—I am, etc.,

Manchester, Sept. 20th. E. Falkner Hill.

HUNGER PAIN AND PRESERVATIVES

Sir,—As I stated in my letter published in the *British Medical Journal* of September 19th, only two preservatives—namely, sulphur dioxide and benzoic acid—are allowed in a limited number of specified articles of food and in certain beverages. I mentioned in that letter all the articles in which one or other of those preservatives is permitted. With the exception of beer the use of preservatives in any of those articles is only allowed on the condition that the nature and quantity of the preservative present is declared on the article as sold. If, therefore, Mr. Forrest's symptoms are due to preservatives it ought to be quite easy for him, in view of these regulations, to trace the cause to one or other of these preservatives.

Mr. Forrest states in your issue of September 26th that his indigestion is provoked by the articles of food to which sulphur dioxide in minute quantities may be added. As the list I gave of those articles is a very short one it will be no great privation for him to omit them from his dietary. He further states: "the preservative that is added to butter brings on the symptoms." I can only assure him that for some years the addition of any preservative to butter, whether made in this country or imported, is forbidden under penalty.

From the perusal of Mr. Forrest's two letters I am driven to the conclusion that he must seek elsewhere than in preservatives in food for the *fons et origo* of his hunger pain.—I am, etc.,

Liverpool, Sept. 26th. Arthur P. Luff.

ETIOLOGY OF PEPTIC ULCER

Sir,—I am very grateful to you for having referred, in a leading article in your issue of September 12th, to my book, *The Causation of Chronic Gastro-Duodenal Ulcers*, and for having drawn the attention of your readers to my conception of a most urgent problem, although your reviewer has come to a somewhat indifferent conclusion as regards the validity of my theory, and has given guarded advice in respect of its application to treatment.

Perhaps you will permit me to comment on the isolated criticism brought forward by your leader writer. He points out what he considers the only weakness in my argument—namely, that I conclude duodenal regurgita-

tion into the stomach to be a pathological mechanism instead of accepting what seems to be the usual teaching (with which he agrees), which says that duodenal regurgitation is a normal physiological function for the reduction of gastric acidity. But what are the facts?

In my book I have given several reasons why the orthodox teaching cannot be accepted. It will now be agreed by all that the contents of the first part of the duodenum are acid, and therefore they cannot have any role in the reduction of gastric acidity. McClendon (*Journ. Biol. Chem.*, 1918, xxxiv, 1) has shown by means of estimation of the hydrogen-ion concentration that the *p*H value of the lower part of the human duodenum varies from 4.5 to 5.1, and, as far as bile is concerned, according to Okada and Arai (quoted by Schmidt, *Physiol. Rev.*, 1927, vii, 129), its hydrogen-ion concentration may vary from 4.7 to 3.4, both reactions being, of course, markedly acid. There is no need to consider the possibility that continual retro-peristalsis may take place from the alkaline part of the intestine, for reasons obvious to everyone. It is worth while to recall that Professor MacLean (*Journ. of Physiol.*, 1928, lxv, 63) has made it quite clear, after most exhaustive investigation, that duodenal regurgitation, as such, is in no way whatever concerned in the reduction of gastric acid. Furthermore, as far as the action of the gastric acid is concerned, it may be worth while to remind your readers that it is accepted by all that acid by itself is not the primary factor concerned in the formation of peptic ulcers, but that some other cause is to blame, which only acts deleteriously in conjunction with the hydrochloric acid.

I now claim that this primary and essential factor concerned in the production of peptic ulcers is bile, when it is in the presence of hydrochloric acid, and I have attempted to justify my claim on physiological, pathological, experimental, and clinical grounds. I therefore leave it to my readers to decide whether I have made out a case for my theory, or whether they will be satisfied to apply the older methods which your reviewer seems to advocate, and which are still a constant bone of contention between physicians and surgeons.

I regret that amongst my other contributions on the subject which contradict the usual interpretation of normal gastric function, only one item was singled out for criticism, and no mention was made of the new conception of the pathology which I have introduced to differentiate between acute and chronic ulcer, and which actually forms the initial and most vital part of my theory. The subject involved is of such vast importance and urgency that any contribution which may further the solution of this problem should at least receive sympathetic consideration.—I am, etc.,

London, W.1, Sept. 26th. J. JACQUES SPIRA.

RADIOLOGY AND THE RADIOLOGIST

SIR,—I cannot lay claim to be the world's clearest writer, but I hoped I had made it quite definite that the radiologist is not asking for any monopoly in the use of *x* rays. What he rightly asks for is adequate training; and if the clinician, without any adequate training, thinks fit to make use of apparatus, by no means simple or danger-free, that is his affair and his responsibility. My personal view, in regard to diagnosis in chest and gastro-intestinal disease, is for the clinical and the radiological investigations to be made by separate people. Such a view is, naturally, not binding upon those who think differently. Several of these latter are my own personal friends, for whom I have the greatest respect, and I think we quite amicably agree to differ.

The future of radiology, as it appears to myself, seems to lie in the direction of closer association of the clinician and the radiologist under the same roof. By this I do not imply the necessity for a clinic, but as individual men, each doing his own job. In such a way I seem to visualize the greater good of the patient, both as regards diagnosis and (may I suggest it?) his pocket.—I am, etc.,

London, W.1, Sept. 27th. STANLEY MELVILLE.

THE RADIOLOGIST AND THE CANCER PATIENT

SIR,—At the present day the position of *x*-ray therapy in malignant disease is practically limited to cases that are, for one reason or another, not amenable to operation, or, after operation, for prophylactic purposes. There is a very natural desire on the part of surgeons and physicians to refrain from telling the victims of malignant disease that they have cancer. This may be, in many cases, quite a right and proper attitude. But the difficulty is that, when these patients are advised *x*-ray treatment (which the public now know is usually given for cancer), they ask why, when they have been given to understand that they have not got this dreaded malady, it is necessary to have this treatment, and, still more, to have repeated series at intervals for at least two years. Radiologists get bombarded with a series of questions most difficult, often impossible, to answer without giving away either the consulting surgeon or physician, or the patient's general medical practitioner, who has been forced to tell the same story as the consultant.

May I make a suggestion? When an operation is performed on a patient with malignant disease, and subsequent *x*-ray therapy is considered advisable, some such statement as this might be given. It could be explained that microscopical examination of what was removed demonstrated that some of the cells showed changes indicating that they were *trying* to become malignant, and that the *x*-ray treatment was advised, and must be repeated, to abort this tendency of these particular cells. The treatment is advised to prevent recurrence and further trouble. By some such explanation as this—which in my experience is seldom given—the patient's mind would be calmed, if not absolutely set at rest, and he or she would realize the necessity for further treatment. Also, the radiologist, and those who had the after-care of the case, would be unhampered in doing their utmost in the circumstances.

Surely it is only loyal to the patient that any utterance of the surgeon or the physician, to whom he has entrusted his life, should be so carefully considered that it cannot be interpreted so as to act contrary to his or her best interest. When it is considered not to be wise to tell the sufferer the whole truth—even though this be communicated to some relative or friend—it is for the physician or surgeon to say so much as will encourage the patient to persevere in what is considered to be to his greatest advantage.—I am, etc.,

as far as possible, to the consideration of the signs, symptoms, and treatment of injuries to the live-born.

As regards the question of the cause of wry-neck, there has been considerable difference of opinion, but I think most of the recent work on the subject shows that the condition is caused by vascular disturbances rather than by direct trauma to the muscle. The subject is discussed at some length by von Reuss[1] and Ehrenfest.[2]—I am, etc.,

Glasgow, Sept. 22nd. GEOFFREY B. FLEMING.

SIR,—Mr. McFarland would be greatly interested to know what evidence I have that there is a rupture of muscle at all, but I hardly think it necessary for me to produce my evidence. In your issue of the previous week (September 19th) there is a letter from Dr. Herbert R. Spencer, the eminent obstetrician, referring to a paper by him in which he showed "that the haematoma is due to bruising, stretching, and rupture at the time of birth." His paper was based on the post-mortem examination of fifteen cases of haematoma occurring in newborn children. Is not this all the evidence Mr. McFarland can possibly require?

But, really, what is the argument about? If Mr. McFarland prefers to think that the muscle is *pinched* at birth, when I think it is bruised, stretched, or ruptured, are we not in agreement? Or, if we are not, could we not become so by saying that the muscle is *damaged* at birth, and leave it at that?—I am, etc.,

London, W.1, Sept. 26th. PAUL BERNARD ROTH.

TREATMENT OF UTERINE HAEMORRHAGE NOT DUE TO UTERINE DISEASE

SIR,—In his excellent article on the above subject (September 26th, p. 556) Dr. James Young does not allude to the use of the galvanic current. In 1900 Dr. A. Zimmern of Paris wrote a lengthy volume on this method. The late Dr. Samuel Sloan of Glasgow discovered it quite independently, and employed it with great success for many years in his practice. He described his method in his *Electricity in Gynaecology*, published in 1917. Both these physicians taught me their technique, and I have found the method astonishingly successful. In the October number of the *Practitioner* I published full details of four severe cases which responded to the galvanic current after all else had failed. (*X* rays and radium had not been tried.) The most striking case of all which I have treated was that of a girl of 22, sent to me by the late Sir John Williams, with the report that she had never had a period in all her life without bleeding continuously for months. She had been twice curetted, once cauterized, and every possible drug and endocrine therapy had been tried. Sir John said that she was sent to me in a very weak condition, after seven weeks of continuous bleeding, and that, if electricity was not successful, hysterectomy was imperative. The treatment had to be begun when there was profuse bleeding and the patient so weak that she could scarcely stand. She was cured, and after eight applications had normal and regular periods for four years. Then she had a relapse, but soon responded to galvanism, and remained normal for over six years, in spite of developing tuberculosis of the lungs. Then a second relapse occurred, for which she is now having a few applications of copper ionization, and is apparently responding as favourably as in the past.—I am, etc.,

London, W.1, Sept. 28th. AGNES SAVILL, M.D.

EPIDEMIC SORE THROAT

SIR,—The following brief account of some cases of sore throat in a country village may be of interest, when taken in connexion with the paper on acute tonsillitis and its sequels, which appeared in the *Journal* of September 19th.

In the latter part of July and the beginning of August there was an epidemic of diphtheria here. On August 6th a boy was brought to my surgery with a highly inflamed throat and a membrane on the right tonsil. I took a swab of his throat, and sent him to hospital as a case of diphtheria. The swabs on all occasions were negative.

Since then I have had some twenty cases of tonsillitis, none of them showing any membrane, but shall confine myself to the mention of eight, all related to the boy mentioned. (1) August 11th, *uncle*—tonsillitis; (2) August 13th, *aunt*—tonsillitis; (3) August 20th, *aunt*—tonsillitis, with transient rash, no desquamation, no complications; (4) August 25th, *grandfather*—tonsillitis; (5) August 28th, *uncle*—tonsillitis; (6) August 28th, *cousin*—tonsillitis, with marked rash, not typically scarlatiniform, desquamation, no albuminuria; (7) September 14th, *father*—tonsillitis; and (8) September 16th, *cousin* (son of Nos. 1 and 2)—scarlet fever. These eight people live in five different houses, mostly at a considerable distance apart; but I think it is obvious that all these cases are different manifestations of the same condition.—I am, etc.,

Isleham, Sept. 22nd. J. W. MCFEETERS.

CONSULTING FEES AND RENTALS

SIR.—I write, in view of the serious economic position, to make the following suggestion: that all consultants shall reduce their consulting fees to £2 2s. during the present stringency, provided that their landlords also reduce their rents to them by 20 per cent. Many of us are paying very high rentals, much in excess of the true present values—so much so that I should think that very few, if any, landlords could obtain such rentals for any fresh agreements or leases. I do not see how we can reduce our fees otherwise, a course that a large number of us would willingly follow were it feasible.

I think there is no doubt that a large number of persons who desire to seek our advice are debarred by the necessarily high fees, and I am sure that, as a consequence, they are seeking our help more and more at the hospitals, thus throwing an increased burden on these institutions. I write in no commercial spirit, for a true doctor will always consider his patient first and his own pecuniary reward second.—I am, etc.,

London, W., Sept. 24th. WILLIAM IBBOTSON.

RHEUMATOID ARTHRITIS

SIR,—There is a suggestion in connexion with rheumatoid arthritis which, as it seems of some interest and practical importance, I venture to send to you.

A feature of this disease which has been little stressed is that, *when occurring in youth*, it is confined almost entirely to the female sex, and is rarely seen in boys. I am not alluding to Still's disease, which attacks children, but to that serious form of true arthritis which begins, in many cases, soon after adolescence. The above observation, which appears to have been little considered, would seem to have a bearing on one of the methods of treatment commonly tried at present—I mean the removal of dead and crowned teeth and tonsils, as being possible sources of the trouble. I would suggest that the virtual sex monopoly of the disease is a strong indication that toxic infection from these centres has no connexion with the causation of the disease, because such infection would

surely not discriminate between male and female If this is so it follows that the removal of teeth or tonsils is futile as a method of treatment

If it is true that the disease does sometimes occur in young males, such cases are nevertheless so infrequent as to leave the point worthy of consideration My contention is also strengthened by the lack of success which, in fact, so often attends these operations In my own case the tonsils were enucleated when I was 20 but, although they were said to be in a septic condition, it made not the smallest difference to the course of the disease, nor, so far as I know, to my health in any way —I am etc,

September 14th "CRIPPLED"

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

This week the National Economy Bill passed through its remaining stages in the House of Commons and was considered in the House of Lords The Commons was also asked to complete its discussions on the Finance Bill In the Economy Bill debate Mr Chamberlain announced that the reduction in the remuneration of panel practitioners would be limited to 10 per cent It is understood that he has indicated his inability to make further concessions in this direction [See opening pages of this week's *Supplement*]

The propriety of an early General Election has been discussed during the week and a very early appeal to the country is expected This would be made by the National Government

The Economy Bill

PROCEEDINGS IN COMMITTEE

On September 25th the House of Commons was in committee on the National Economy Bill and considered the services in respect of which Orders in Council restricting expenditure might be made under the Statute

The Health Insurance Cut

Mr REES DAVIES moved to omit from this schedule the words national health insurance He said the Minister of Health had issued a White Paper which would lead the House of Commons to believe the panel doctors were generous enough to hand over to the Treasury £850 000 per year of their own money The case was not exactly like that What happened apparently was that the Minister of Health went to the British Medical Association and asked it to come to the rescue of the pound sterling Panel doctors were paid a 9s capitation grant in respect of the fifteen million insured persons in the country Except for a small contribution from the Exchequer that 9s came out of the funds of the approved societies and if the 9s was reduced the reduction ought to accrue to the funds of the approved societies from which it came After the Minister of Health had made an agreement with the British Medical Association he came to the representatives of the approved societies on the Consultative Council and informed them of it The contract for this reduction was practically completed before the approved societies had a chance to say a word about it The proposal the House was considering made a cut of 1s in the fees of panel doctors Only in respect of national health insurance did the Government propose cuts going beyond the May Economy Committee's recommendations

Mr CHAMBERLAIN (Minister of Health) asked how Mr Davies reached that conclusion

Mr DAVIES replied that the May Committee suggested a saving on health insurance of £1 000 000 but the Bill suggested £1 100 000 He asked whether the approved societies would get the same service from the doctors for 8s that they were now getting for 9s Since the Minister of Health had made this arrangement with the chemists one of the largest chemist firms in this country had asked their staff to accept a reduction in wages as a consequence of the proposed reduction of the grant It was claimed that the chemists would hand over £120 000 to the Treasury but the staff of this one firm would suffer a reduction of wages probably amounting to that sum The firm might make a profit out of the transaction Mr Davies declared that the Government was receiving stolen property The doctors and the Ministry of Health had arranged to hand over to the Treasury approximately one million pounds which did not belong to them but to the societies as a body He did not criticize the professional ethics of the doctors but he was afraid they might as a result increase their charges to their non-panel patients He doubted whether in the end the doctors would suffer much

Dr MORRIS JONES remarked that the panel doctors had suffered a cut of over 10 per cent, whereas no reduction had been made in the amount given to the approved societies for administration He thought that amount ought to be reduced now

Mr DAVIES said it was appropriate to ask whether patients would get from the panel doctors in future the service they were getting now and the same quality and the same standard of drugs from the chemists as now In 1913 there were 12 674 panel doctors In 1930 there were 15 750 The average income of each panel doctor was £304 in 1913 to £463 in 1930 an increase of about 50 per cent Mr Davies added that he did not think the medical profession was overpaid but the May Committee had made a scathing attack upon the capitation payment to panel doctors That committee said municipal authorities found it difficult to secure the services of medical men because the fees under the national health insurance scheme were so much lower The May Committee pointed out definitely that 9s was too much because under the old friendly societies system the figure was 2s 6d Every Government had made a raid on health insurance funds and in result would be a reduction of benefits Statutory benefit would not be reduced at the moment but dental optical convalescent home and distress grants would probably go by the board in consequence of these raids In the end this reduction to the Treasury would make it certain that people on permanent disablement benefit would receive not 10 out 7 6d If the Government reduced the doctors' fees by £1 000 000 and handed over that sum to the Treasury that money must come from one fund or the scheme Whenever fees had been reduced in the past that reduction had always accrued to the funds of the societies Mr Davies concluded by declaring that the panel doctors and approved societies had helped considerably to reduce the general mortality rate and infantile mortality By taking away money from the scheme the Government damaged the health of the whole community

Minister of Health's Pep!

Mr CHAMBERLAIN said that Mr Davies really knew something about national health insurance and there was no excuse for his attempt to represent the action which the Government proposed as a raid upon the funds of societies Mr Chamberlain denied he had ever told the House that the societies had agreed to take a shilling from the capitation fees of the doctors and hand it to the Exchequer In the ordinary course any arrangement reducing the capitation fee would benefit the funds of the societies But this was not the ordinary course The doctors were asked whether they would agree to a reduction in their remuneration as a contribution to the national needs and not to the societies funds If the latter had been asked to give up 1s simply for benefiting the funds of the societies they would have refused and would have fought the case to the end They asked whether Mr Chamberlain could give an assurance that anything they gave up would go to the Exchequer and not to the societies It was quite clear that he asked them to accept the cut and they agreed to it The contribution of the doctors was the pecuniary equivalent which the May Committee had recommended That committee estimated a saving thereby in a full year of £750 000 A closer estimate showed that it would be £850 000 but there was no difference in principle He did not know why the May Committee did not recommend any reduction in the remuneration of the chemists If the doctors were asked to make a contribution it was reasonable and right that the chemists also should contribute and the chemists also agreed

Mr Chamberlain then announced an additional reduction of the figures in the White Paper He recalled that the Prime Minister had announced alterations in the cuts originally proposed for the Defence Services for the police and for the teachers For these there was to be a maximum of 10 per

cent instead of the varying rates previously proposed The cut of 1s from the doctors represented 11 per cent Mr Chamberlain thought it unfair to them, and inconsistent with the general scheme of the Government that, when an alteration had been made, the doctors and chemists alone should be left out of it Accordingly he had written to the Insurance Acts Committee of the British Medical Association, and also to the Pharmacists' Union, and said the Government proposed to substitute a simple 10 per cent reduction in both cases That meant the economy would be lessened by about £90 000 in a full year, which he hoped to make good by savings in other directions Mr Chamberlain went on to say that the approved societies were relieved at the proposals the Government made in connexion with the Central Fund of the health insurance scheme Owing to the enormous increase in the claims for sickness benefit the position of a number of societies after the next valuation would be much less satisfactory than after the last Without outside help some societies might not even be able to meet the statutory benefits It was true that £142,000, which would fall to be paid this year from the Exchequer, was not to be paid, but instead of that the Central Fund would get £300 000 per year which it had not had before, and also arrears of that £300 000 since 1928 That would amount to something like £1,000 000, placing the Central Fund in an unassailable position and guaranteeing the standard benefit all round There was no raiding of the funds, and approved societies would be made stronger by the Government proposals

Mr THOMAS LEWIS said that the money under discussion was at the present time the property of the approved societies Formerly the Government made a grant in respect of the payment of doctors but that grant was subsequently withdrawn, and the societies were made to contribute 13s to the Medical Fund, of which 9s went in payment of doctors Some societies had felt for a long time that the doctors were being overpaid He was a member of the Consultative Council in connexion with health insurance, and he believed that council had agreed to the Government's proposals, though he himself demurred It was a gross impertinence to hand over other people's money in this fashion It was very nice to give up one's own money out of goodness of heart, but to make a sacrifice on somebody else's behalf savoured of very great impertinence National health insurance required the funds for it was in a precarious state A number of small societies could not to day pay the statutory benefits, and it was expected that on the fourth valuation a very large additional number would be unable to meet that benefit Exchequer grants to the system were now £4,000,000 less per year than they were ten years ago Receipts and payments to the scheme were just balancing He feared that the reform which was imperative with regard to maternity benefit was going to be delayed The Consultative Council had considered this for many years, and it had reached the final stage in regard to the halving of the grant of £2 per head, so that £1 could be used for building up a new service of maternity homes He hoped the Minister of Health would not allow that to go by the board

Dr MORRIS JONES said that the medical profession would be pleased with, and the House as a whole would gladly accept, the offer which had been made by the Minister of Health It would not have been right, after the profession had accepted the cuts, not on their merits, but in a time of emergency, that they should be penalized for taking quietly what a number of other professions had not accepted He was disappointed at the attitude of Mr Davies He had expected him to say that the medical profession had behaved extraordinarily well in this instance While thanking Mr Chamberlain for the 1 per cent concession, Dr Morris Jones asked, on what principle of equity the 4s 6d per head allowed for administration expenses for approved societies remained unaltered There had been no cut there, although the financial situation of the societies was such that they could bear a small reduction per head for administrative expenses That would have produced some small sum for the State, and have given the approved societies an opportunity of following the very patriotic example of the medical profession.

The House then divided, and by 237 votes to 153 retained national health insurance in the schedule of the Bill

During the resumed debate on the Economy Bill, on September 28th, Mr SOMERVILLE HASTINGS said that during the past week they had talked a great deal about the gold standard, and whether it ought to be maintained or not He thought that the man standard of this country was of greater importance We could not afford to neglect anything which would help to maintain our man power, whether employed or unemployed, at the highest possible level of fitness and efficiency We must depend upon such efficiency in producing the goods which were required to pay for our food and other imports If the standard of living of the unemployed were lowered the consequences might be serious When an unemployed man found a difficulty in obtaining work he felt that he was not wanted, and if, added to that, there was destitution, the mental effects might be serious Fortunately, in this country, we had not seen anything of that kind, but in other countries, where the unemployed were differently treated, it had led to an increase in suicide and crime

On September 29th the Economy Bill was read the third time in the House of Commons

Dr DRUMMOND SHIELS, in opposing, remarked that little had been said about the doctors and chemists He had always found it very difficult to work up sympathy in the House for doctors, and sometimes for chemists, but they were said to have taken their medicine without flinching It had been hinted by one member that they were at the time unaware that more income and petrol taxes were awaiting them What their present state of mind might be was not stated, but here, again, the real attack was not on the doctors and the chemists but on the social services of which they were a part The Royal Commissions had shown that the national health insurance system, while good so far as it went, was quite inadequate Members who knew those reports knew that the improvement of specialist service and services for dependants and many other developments, were required before it could be said to be an adequate service for its purpose Yet, instead of improvements, we had this setback, and the standard of working class medical service was definitely lowered compared with that of other sections of the community He was referring to the developments foreshadowed by the Royal Commission This national health insurance was a vital service It was one of the things which were not often sufficiently emphasized, in view of the wonderful developments of medical and surgical skill, that these ought to be available in full and ample measure to the very humblest members of the community They were not so just now, and the gesture of this Bill in regard to that service was definitely to lower its status

By a majority the Bill was read a third time and sent to the House of Lords

---

Control of Imported Milk

On September 24th, replying to Colonel Gault, Mr CHAMBERLAIN said the laws as to adulteration applied equally to liquid and frozen milk, with the added safeguard, in the case of imported milk, that it was subject to sampling at the time of importation The regulations also required that imported milk should be free from tubercle bacilli, and should not contain more than 100,000 bacteria per cubic centimetre These conditions were at least the equivalent of those which applied to English milk Colonel Gault, in his question asserted that milk is now imported into England frozen into solid blocks

---

Medical Care of Prisoners.—Replying to Sir C Rawson on September 24th, Sir H SAMUEL said there was no reason why a prisoner in Parkhurst Prison, who suffered from angina pectoris, should be visited by his own doctor, as he was receiving all necessary medical care and attention, and had been free from heart attacks during his sentence If necessary, the prison medical officer could call in a specialist

Meals for School Children.—Sir D MACLEAN told Mr Tinker, on September 24th, that in the week ending July 18th, 134 local education authorities made provision for the feeding of school children The number of children receiving meals was approximately 154,500, of whom 101,500 were necessitous children receiving meals free of charge Sir D Maclean told Mr E Williams, on the same day, that he had no statutory power to authorize local education authorities to provide boots for necessitous school children, or to make a special grant for this purpose

Obituary

Sir William John Ritchie Simpson, C.M.G.

M.D., F.R.C.P.

Director of Tropical Hygiene, Ross Institute

We have to record with deep regret the death of Sir William Simpson, which occurred at the Ross Institute on the night of Sunday, September 20th. He had been in his usual health the week before but developed a cold which passed into pneumonia with fatal results. Born in Scotland on April 27th, 1855, Simpson was thus 76 years of age. He was educated at Aberdeen University, where he graduated M.D. in 1880. He soon decided to devote himself to the study of public health, and took his D.P.H. at Cambridge in 1880. He was then appointed health officer for the City of Aberdeen. After this he came to London and studied at King's College. In 1886 he went out to Calcutta as health officer and remained there until 1897. It was here that he gained his tropical experience. On his return to London in 1898 he was appointed professor of hygiene in King's College, and also lecturer in tropical medicine at the same place. When Sir Patrick Manson was forming the London School of Tropical Medicine in 1899, Simpson joined the staff with Cantlie, Duncan, Baker, Howlett, and Sambon. There he lectured on tropical hygiene, and held the appointment until 1923, when he retired on the age limit. After this, however, Simpson was not finished, and he had much vitality left. When the Ross Institute was founded he became director of tropical hygiene there, and put much energy into furthering the development of that institution. He became a Fellow of the Society of Tropical Medicine and Hygiene in 1909, served on the council from 1911 to 1917, was vice-president from 1917 to 1919, and president from 1919 to 1921. He chose for the title of his presidential address "Some considerations regarding preventable diseases and their prevention." During his period of office he was instrumental in getting the society raised to the position of a royal one, and from that date always took the greatest interest in its affairs. He supported strongly the move to Manson House, where the society is now installed, and it is sad to think that he will not see the opening of the new building on its completion.

During his career Simpson held many other important posts, for example he was a member of the Naval Medical Consultative Board, of the Colonial Medical and Sanitary Committee of the Yellow Fever Commission in West Africa, and of the Government Commission on Enteric Fever, South Africa, 1900–1. He also served on a Government Commission to inquire into the causes and continuance of plague in Hong Kong, 1902, and to report on the sanitary condition of Singapore in 1903; West Africa, 1908; East Africa, Uganda, and Zanzibar, 1913–14; and of mines and mining villages of the Gold Coast as regards the prevalence of plague there, 1924.

Sir William Simpson.

Writing also did not come amiss to him. He was editor of the *Indian Medical Gazette* from 1889 to 1896, and editor of the *Journal of Tropical Medicine* in the old days and up to the present time. While in India he became interested in plague, and in 1905 published an interesting and valuable monograph upon the disease. In addition to this, he published a textbook entitled, *Maintenance of Health in the Tropics* (1916), a previous work published in 1908 being termed *The Principles of Hygiene in Relation to Tropical and Subtropical Climates*. He delivered the Croonian Lectures at the Royal College of Physicians in 1907.

He was elected a Fellow of the Royal College of Physicians in 1899, was made C.M.G. in 1909, and received the honour of knighthood in 1923. During the war he undertook service in Serbia, and was given the Order of St. Sava of Serbia in 1918. He married Mary, daughter of the Rev. Dr. Jamieson, St. Machar Cathedral, Old Aberdeen. He lost his son in the war, and is survived by his widow and a daughter.

Simpson was liked by all and had no enemies, and he was always delighted to help young men in forming their careers. Though of a kindly disposition he was possessed of great determination, which in certain instances brought him into conflict with those with whom he had to deal. This determination is well illustrated by his recent tour to Rhodesia on behalf of the Ross Institute, an undertaking which might have deterred even a younger man. Lately he had been much interested in London's open spaces, which were being encroached upon by modern building operations. He did his best by illustrated pamphlets and other means to check this retrograde step, which he was convinced was bad for the health of London's population.

Simpson may be termed one of the pioneers of tropical medicine, one of that band of workers who did so much at the beginning of the century to develop the Tropics and make them healthy and habitable for the white races. Dr. Sambon, another of these, passed away only the other day; they were lifelong friends, and were much devoted to each other.

G. Carmichael Low.

Sir William Simpson was vice-president of the Section of Tropical Medicine at the Annual Meetings of the British Medical Association in 1898 and 1913, and president in 1914.

Sir Harry Baldwin, C.V.O.

M.R.C.S., L.D.S.

Honorary Surgeon Dentist to the King

We announced briefly in last week's *Journal* the death of Sir Harry Baldwin, honorary surgeon dentist to the King. While cruising in his motor yacht *Mal de Mer* off the Brittany coast he contracted typhoid, and after three weeks' illness died in hospital at Vannes, France, on Sunday, September 20th.

Harry Baldwin was born at West Bridgford, Notts, in 1862, and was educated at Nottingham High School. Thence he went to Middlesex Hospital and the Royal Dental Hospital of London for his medical and dental training. On qualifying in 1884 he joined the late Sir Charles Tomes in dental practice in Cavendish Square, and for many years attended Queen Victoria; later, in 1918, he was appointed surgeon dentist to the King, and in 1926, on his retirement from practice, honorary surgeon dentist. He was knighted in 1918, and made C.V.O. in 1923.

From 1891 to 1899 he served the Royal Dental Hospital as assistant dental surgeon. In 1913 he was president of the Metropolitan Branch of the British Dental Association, and in 1915 of the Odontological Section of the Royal Society of Medicine. In 1912 he was president of the British Society for the Study of Orthodontics, and for many years was treasurer of the British Dental Association. During the war he was consulting dental surgeon to the military hospitals of London, and again undertook the work of dental surgeon to the Royal Dental Hospital.

Sir Harry Baldwin made two outstanding contributions to the progress of dental surgery—he popularized in England the use of plaster-of-Paris in taking impressions of the mouth, and he originated a method of combining cement and amalgam in filling a tooth which has resulted in saving large numbers of apparently hopelessly decayed teeth. His professional standard was of the highest, and his skill in all branches of his profession made him worthy of all the honours and success that fell to his lot. As a junior surgeon to the Royal Dental Hospital, the writer of this notice served with Sir Harry (then Mr.) Baldwin, and vividly remembers how the self-reliance and keen analytical acumen of his senior helped him through many a difficult case.

Like his partner, Sir Charles Tomes, he was an excellent artist, and, under an assumed name, had exhibited at the Royal Academy. He had, too, an expert's knowledge of etchings and of Chinese porcelain ware. On his retirement he went to live at St. Helens, Isle of Wight, where he took up golf and shooting, and, in spite of the fact that he had neither played golf nor shot before, rapidly became proficient in both sports. Later he took up motor-cruising, which led to his untimely death from a disease which sanitary science should have banished long since.

The whole dental profession will mourn and miss him, especially those who, like the present writer, knew him intimately and felt his personal charm. He leaves a widow and a daughter.

J. G. T.

W. F. DEARDEN, M.R.C.S., L.R.C.P.

Medical Officer of Health, Manchester Port

Dr. William Francis Dearden of Manchester died in hospital on September 15th, after a short illness which ended very suddenly when he was confidently expecting relief and ultimate cure from operation, and was full of plans for the future. By his death the medical profession has lost one of those quiet, unobtrusive, and efficient workers who are so ill spared in any community. Qualifying in 1885 as M.R.C.S. and L.R.C.P., he spent some years in general practice—a good training, as he always admitted, for his long and distinguished service as medical officer of health to the Manchester Port Sanitary Authority, and as factory surgeon to this area. He was honorary secretary to the Association of Factory Surgeons, made many contributions to the literature of industrial hygiene, was one of the first to call attention to the incidence of epithelioma among cotton spinners, and in 1927 gave the Milroy Lecture before the Royal College of Physicians of London on "Health hazards in the cotton industry."

Very early in his career Dearden became interested in public work, and though he represented his ward in the city council for some years, this interest was soon centred in work for the British Medical Association and his professional colleagues. Mention of the offices held by him can but outline our indebtedness and indicate the range of his service. Locally, he was representative, chairman of the North Manchester and later of the combined Manchester Divisions, and charities secretary; and outside the Division he was a member of the Charities and Public Health Committees of the Association, and served as secretary of the Section of Industrial Hygiene and Diseases of Occupation at the Annual Meeting of 1902, vice-president of the Section of Industrial Diseases in 1908, and president of the Section of Occupational Diseases in 1929. In Stretford—the district in which he resided—he was past-president of the local medical society, and chairman of the medical board of the Memorial Hospital—a general practitioners' hospital organized mainly on the lines since adopted by the British Medical Association in its Hospital Policy.

But probably he would himself have wished—and many of his colleagues would agree—that the highest meed of appreciation and gratitude should be reserved for his really great work as secretary of the Manchester Medical War Committee. To this Dearden gave of his best, and it was a great satisfaction to him that as a result of that work the interests of the medical services of Manchester and of her absentee doctors were so well conserved that those who returned found that their practices had suffered none but the inevitable damage. It was a point of honour with him that this work should be its own reward, and he firmly declined to accept a decoration offered him on its conclusion.

Reserved, quiet, of high standing in the chosen branch of his profession, even keener on work for his professional brethren, it is impossible to assess our loss. There has been no medical movement in Manchester for the past thirty-five years that has not been helped by Dearden's active support and wise counsel; those of us who have had the privilege of working with him know what a loyal friend and hard worker we have lost; and the heartfelt sympathy of all goes to his wife and daughter.

R. G. M.

Sir Thomas Legge writes:

A foremost interest in Dearden's life was his participation in the work of the certifying factory surgeon; for over thirty years as honorary secretary, and then as president of the Certifying Factory Surgeons' Association, he was indefatigable in his efforts to consolidate and strengthen it. No trouble was too great for him to take in that interest, by deputations to the Home Secretary, to increase the fee and scope of the work, in organizing an Industrial Disease Section at meetings of the British Medical Association, in advancing their status, and tracing their honourable history over the past century of their existence. He recognized that the shortcomings in their work were not due to the men, but to the narrow statutory requirements of the section of the Factory Act under which they have to work. He deplored the negative character of the certificate of fitness, and the lack of power to follow up and re-examine. He lived to see this negative certificate converted into a positive one—namely, that the employee is fit for employment "for the full time allowed by law," which, if not yet statutorily enforced, is at any rate embodied in both the Factory Bills which have been published, the one by a Labour and the other by a

Conservative Government. And in his own district, in an important branch of the cotton industry, and the india-rubber industry, he was able to achieve this object. He took immense interest in other branches of factory hygiene, reporting on notifiable industrial diseases, on gassing cases, in his monthly examination of workers under Home Office Regulations for the india-rubber industry, and in his work under the Workmen's Compensation Act.

RICHARD WHYTOCK LESLIE, M.D., M.Ch., LL.D.

Consulting Physician to the Ulster Hospital for Children and Women

We much regret to announce that Dr. R. W. Leslie died on September 22nd at a nursing home in Belfast after a few weeks' illness. By his death the medical profession of Northern Ireland loses a trusted leader and representative.

R. W. Leslie, M.D., LL.D.

Richard Whytock Leslie was born in County Tyrone on September 26th, 1862. His father was the Rev. John Knox Leslie of Cookstown. From Raphoe Royal School he went to University College, Galway, and thence to Queen's College, Belfast, graduating M.D. and M.Ch. at the old Royal University of Ireland in 1887, having obtained in the previous year the L.M. of the Rotunda Hospital, Dublin. A large part of Dr. Leslie's active professional career was spent in Belfast, where he served for thirty-five years as physician to the Ulster Hospital for Children and Women in Templemore Avenue; he was also physician to Campbell College, Belfast. For many years he gave up much of his leisure to the work of ambulance instruction, serving as examiner and medical secretary of the Ulster Branch of the St. John Ambulance Association. For several years he conducted a first-aid class in the city of Belfast, particularly in the Strandtown district, where he won the respect and affection of all classes. In recognition of his services, more particularly during the war, he was created a Knight of Grace of the Order of St. John of Jerusalem.

In 1905 Dr. Leslie was elected a senator of the Royal University of Ireland, and in 1909, when Queen's College was merged in the new Queen's University of Belfast, he received the honorary degree of LL.D. As a senator of Queen's University and a member of convocation he undertook many duties, including membership of the Standing Committee, the Committee for the Extension of University Teaching, the Committee on Military Instruction, the Athletic Field Committee, the Committee to Administer Research Funds, and the Board of Curators. He was an active member of the Ulster Medical Society, in which he held office as president in 1912-13. In politics Dr. Leslie was devoted to the Unionist cause; he was a member of the Ulster Unionist Council and of the Queen's University Voters' Association. An influential Freemason and a warm supporter of masonic charities, he was Past-Master of Acacia Lodge, and one of the founders of Queen's University Lodge.

To the work of the British Medical Association, both locally and at headquarters, Dr. Leslie gave much time and thought. He was chairman of the Belfast Division in 1919-20, a member of the Irish Committee from 1922 onwards, and a member of the Central Council from 1923 to the time of his death. He was diligent in attendance at Council meetings in London, though never prominent in debate. When the Association held its Annual Meeting in Belfast in 1909 under the presidency of Sir William Whitla, he was vice-president of the Section of Diseases of Children. He had also served as president of the Ulster Branch.

Mr. C. J. A. Woodside, F.R.C.S., honorary secretary of the Ulster Branch, sends the following personal tribute:

Dr. Leslie practically never missed a meeting of council or a general meeting of the Branch. His interest in every detail of the work never flagged. With others who had so many interests, and especially who took such an active part in the work at headquarters, one would have been hesitant in seeking help in minor affairs, but in the case of Dr. Leslie, no matter what the difficulty, I never hesitated to seek his help and advice. His good nature, geniality, sincerity, his wisdom, and his competence, were a combination of virtues seldom found in one man. His place in the British Medical Association will not soon be filled, nor will those who knew him soon forget him.

[The photograph reproduced is by Lafayette, Dublin.]

Dr. Frédéric Wanner, tutor to British post-graduate medical students, 1924-31, died at Lausanne on September 12th. He was privatdocent de l'Université, and since 1925 also Chef du Service Sanitaire Cantonal, and also Vice-Président du Conseil du Santé. His death at the age of 54 will be learnt of with deep regret by his old students all over the world.

The following well-known foreign medical men have recently died: Dr. Siegfried Rabow, first professor of psychiatry and subsequently of pharmacology at Lausanne, and author of a work on prescriptions which went through several editions; Dr. Charles Karsner Mills, emeritus professor of neurology in the University of Pennsylvania, and corresponding member of the Section of Neurology of the Royal Society of Medicine, aged 85; Dr. Hobart Amory Hare, professor of therapeutics at the Jefferson Medical College of Philadelphia, and author of works on therapeutics and complications of typhoid and other fevers, aged 68; and Dr. Lawrence Webster Fox, a Philadelphia ophthalmologist, aged 78.

The Services

PRESENTATION TO SIR G GUISE MOORES

Major General Sir G Guise Moores, K C B, was presented on September 25th with a silver tray, tea and coffee service, and entree dishes, and a settee and two armchairs, from the officers who have passed through the King Edward Convalescent Home for Officers at Osborne, together with the matron and nursing sisters during his seven years' term of office as house governor and medical superintendent The presentation was made by Colonel D J J Hill, who eulogized his work at Osborne Sir G Guise Moores will be succeeded as house governor and medical superintendent at Osborne by Major-General Godfrey Late on October 9th

DEATHS IN THE SERVICES

Colonel Edward Patrick Connolly, late R A M C, died at Kingstown, Ireland, on August 5th aged 54 Born in 1876, the eldest son of D I G William Connolly R N (ret), he was educated at the Catholic University, Dublin, and took the *L R C P and S I in 1898 After being resident surgeon at* St Vincent's Hospital Dublin he entered the R A M C as lieutenant in 1899, became lieutenant colonel in 1915, colonel in 1927, and retired early in the present year, when holding the post of A D M S in Northern Ireland He served throughout the South African war being awarded the Queen's medal with five clasps and the King's medal with two clasps, and in the Tibet expedition of 1903 4, receiving the medal with clasp He also took part in the great war

Lieut Colonel Leopold App Arthur Andrews, R A M C (ret) died at Beckmeadow *Mundesley, Norfolk, on August* 6th aged 49 Educated at the school of the Royal College of Surgeons in Ireland he took the L R C P and S I in 1906 and entered the R A M C as lieutenant in the following year After service in the great war he became major in 1919 and retired with the honorary rank of lieutenant-colonel in 1928

Universities and Colleges

UNIVERSITY OF LONDON

LONDON HOSPITAL MEDICAL COLLEGE

The following scholarship awards have been made at the London Hospital Medical College Prize Scholarship in Science (£100) Mr G K Taylor Entrance Scholarship in Science (£50) Mr P H Tooley Scholarship open to students of Epsom College Mr R B Taylor Scholarships open to students of Universities of Oxford and Cambridge (1) Price Scholarship in Anatomy and Physiology (£100), Mr T L R Shore, (2) Freedom Scholarship in Pathology (£100), Mr A M Birrell Two open Scholarships (each of the value of £100), Mr G E Godber and Mr G W Hayward

The Schorstein Memorial Lecture will be delivered by Dr. Arthur J Hall, professor of medicine, University of Sheffield, in the Bearsted Clinical Theatre on Thursday, October 15th, at 4 15 p m, the subject will be "Chronic epidemic encephalitis" Members of the medical profession are cordially invited

A post graduate course for former students will be held on October 14th, 15th, 16th and 17th, and the old students' dinner will take place at the Trocadero Restaurant on Thursday, October 15th

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The second course of five Heath Clark Lectures on the rise of preventive medicine will be given by Sir George Newman K C B, on October 13th 15th, 16th, 20th, and 22nd at 5 p m

UNIVERSITY COLLEGE

A course of six lectures on the physiology of the sense organs will be given by Dr R J Lythgoe on October 12th 19th 26th, and November 2nd 9th, and 16th, at 5 p m

Four lectures on speculation observation, and experiment, as illustrated by the history of embryology, will be given by Dr Joseph Needham on October 14th, 21st, 28th, and November 4th at 5 30 p m

Dr L L Bayliss will give a course of four lectures on the respiratory functions of the blood, on October 16th, 23rd, 30th, and November 6th at 5 p m

KING'S COLLEGE

Four lectures on metabolism of the carbohydrates and fats will be given by Dr J A Hewitt on October 15th, 22nd, 29th, and November 5th, at 5 p m

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated

M D—J Phillips

Final M B Ch B—Part I: J H Hudson, J H Lawrence, R Raines *Part II* N W Roberts, M G Ross, C K Shum R J Tunbridge, Ethan I Waller *Part III* R J Tunbridge (second class honours), L Glick, J M Holmes, G Hyman H Mattison, N W. Roberts, M G Ross, B Schroeder, Ethan I Walker

DIPLOMA IN PUBLIC HEALTH—Catherine M Gray

The William Nov Medal and the West Riding Panel Practitioners' Prize have been awarded to P R Allison

LAUSANNE MEDICAL GRADUATES

The following have received the M D degree from the University of Lausanne during the last academic year (October 1930 to July, 1931): Miss Louise M Poynder, Colin McIver Major I M S The following have passed the examinations, and are now qualified to present a thesis for the degree of M D Owen Henry Bellerby, G K Kee, Edwin M Robertson The university opens for the academic year 1931-32 on October 15th

Medical News

The new winter session at Guy's Hospital Medical School will open to-day (Friday, October 2nd), at 3 p m, when Sir Farquhar Buzzard, regius professor of medicine in the University of Oxford, will deliver an address and distribute the prizes. The subject of the opening address is "The General Medical Council"

At the opening of the ninetieth session of the School of Pharmacy of the Pharmaceutical Society of Great Britain, on Wednesday, October 7th, at 3 o'clock, the inaugural sessional address will be given by Professor G E Gask, dean of the Faculty of Medicine, University of London

Sir James Jeans, F R S, will speak (under the auspices of the British Institute of Philosophy) on "The mathematical aspect of the universe," at University College, Gower Street, W.C, on Tuesday, October 13th, at 8 15 p m Tickets (for which there is no charge) can be obtained from the Director of Studies, University Hall, 14, Gordon Square, W.C.1.

The presentation of medals and prizes in the Faculty of Medicine of Birmingham University will take place on Tuesday, October 6th, at 5 p m, in the Medical Lecture Theatre, the University, Edmund Street An address to students will be given by Professor Leonard Gamgee, Ch M, F R C S Tea at 4 30 p m in the University Club

The Hunterian Society of London will open its new session on Thursday, October 22nd, with a dinner meeting at Simpson's Restaurant, Cheapside, when Dr David Ross will give his presidential address on "Some problems of gout" The subject for discussion on November 16th is "The medical aspects of crime in fact and fiction," and on December 17th "Oral sepsis" The Hunterian Lecture will be given on January 18th by Professor von Eiselsberg of Vienna, entitled "How Roentgen has helped in modern surgical diagnosis."

Mr Maurice Sorsby will deliver the presidential address on "Deafness and its prevention" before the London Jewish Hospital Medical Society on October 8th, at 3 30 p m, at the London Jewish Hospital, Stepney Green, E Lord Moynihan, President of the Royal College of Surgeons, will be the guest at the annual dinner to be held on Thursday, December 10th, at 7 30 p m, at the Trocadero Restaurant

A short course of lectures on functional nervous disorders, for practitioners and medical students, will be given at the Tavistock Square Clinic from November 2nd to 14th inclusive Sessions will be held at 4 45, 5 45, and 8 15 p m on Monday, Tuesday, Wednesday, Thursday, and Friday of each week, and there will be demonstrations on the Saturday afternoons from 2 30 to 5 o'clock The fee for the course is £2 2s for medical graduates and 10s 6d for students, tickets to be obtained in advance from the honorary lecture secretary, 51, Tavistock Square, W C 1.

The Fellowship of Medicine and Post Graduate Medical Association announces that the first of a series of eighteen evening lectures for the M R C P examination will be given at the Medical Society of London 11, Chandos Street W 1, at 8 30, on Monday, October 5th, by Dr W Langdon Brown on The clinical importance of blood sugar high and low, followed on Wednesday, October 7th by Dr L J Witts on 'Achlorhydria' Fee 10s 6d each lecture payable at the lecture room, or £6 6s for the series The following courses will begin on Monday, October 5th At the Central London Throat, Nose, and Ear Hospital for four weeks including a clinical course, fee £5 5s, or £2 2s for the first week only, and at the Hospital for Tropical Diseases 25 Gordon Square, in tropical medicine occupying the whole of each day, fee £8 8s for three weeks Other courses in October will include gynæcology at the Chelsea Hospital for Women October 12th to 23rd fee £5 5s cardiology at the National Hospital for Diseases of the Heart October 12th to 23rd fee £7 7s, diseases of children, at the Hospital for Sick Children mornings only, October 19th to 31st fee £5 5s (this course will only be held if a minimum of ten post graduates take it, and early application is therefore essential) A series of free lectures on Prognosis will be given on Wednesdays at 4 p m at the Medical Society of London 11, Chandos Street Cavendish Square beginning on October 14th Copies of all syllabuses are obtainable from the Fellowship of Medicine 1 Wimpole Street W 1

A short course of lectures on contraceptive technique will be given without fee at the Royal Institute of Public Health (37 Russell Square W C 1) on Thursdays November 12th 19th and 26th, at 4 p m In association with the lectures clinical demonstrations will be held at 108 Whitfield Street W 1 on the afternoons of Wednesday November 4th and Wednesday, December 2nd Applicants desirous of attending the demonstrations must send in their names to the clinic in advance and obtain tickets These will be limited to members of the medical profession and senior medical students attending the lecture course at the institute

The fourth Annual Graduate Fortnight at the New York Academy of Medicine will be held from October 19th to 30th The subject for consideration will be Disorders of the circulation,' and an extensive programme of lectures clinics, and demonstrations has been drawn up Further information may be obtained from the New York Academy of Medicine 2, East 103rd Street New York

A course of lectures on the health of the citizen will be delivered at the Royal Institute of Public Health (37 Russell Square, W C) on Wednesdays, at 4 p m, from October 14th to December 16th inclusive The lecturers include Sir Ernest Graham Little Sir Leonard Hill Professor F J Browne Dr L E Claremont (Director Eastman Dental Clinic Royal Free Hospital) Professor Winifred Cullis, Dr Chalmers Watson Dr David Lees Professor H R Kenwood, Professor Edgar L Collis and Sir Pendrill Varrier Jones The course is intended primarily for the Fellows and Members of the Institute but all others interested in medico-sociological problems are invited to attend

The annual meeting of the French Society of Gynæcology will be held at the Paris Faculty of Medicine on October 5th when the following papers will be read (1) A report by M Paul Ulrich of Paris, on the chemistry of the vagina and its physiological significance, followed by a paper by M C Guillaumin of Paris on the best chemical conditions for the development of different organisms in the vaginal secretions, (2) Indications for operation in chronic non tuberculous salpingitis, by M Ch Martin of Angers

A general meeting of the Guild of St Luke, St Cosmas, and St Damian will be held in the Cathedral Hall Archbishop's House Westminster, on Sunday, October 18th immediately after High Mass in the Cathedral at 10 30 a m In the annual report for the year 1930 31 it is stated that the council had decided that it was not advisable for the Guild to participate in any official manner at public meetings on the subject of Lourdes the council decided further, to take no action that might in any way derogate from the competence and value of the medical bureau at Lourdes The Irish membership of the Guild is increasing, particularly in Dublin, and the formation of an autonomous Irish branch is under consideration Reference is made in the report to the successful meeting of the Guild held at Eastbourne during the Annual Meeting of the British Medical Association

The fortieth French Congress of Surgery will be held at the Paris Faculty of Medicine from October 5th to 10th, when the following subjects will be discussed post operative peptic ulcers introduced by MM Gosset of Paris and Leriche of Strasbourg, pneumococcal peritonitis introduced by MM Brechot of Paris and Nové Josserand of Lyons and immediate treatment of compound fractures of the leg, introduced by MM Roux of Montpellier and Senegue of Paris

The Salon des Medecins for the exhibition of works of art by doctors, dentists veterinary surgeons pharmacists and members of their families will be held at 117 Boulevard Saint Germain from October 4th to 12th

We are informed that in view of the general economic depression the Aerzte Verein Davos has decided to postpone until 1932 the conference on tuberculosis which was to have been held this year at Davos from October 5th to 10th

Messrs Edward Arnold and Co announce for early publication *The Rheumatic Infections in Childhood* by Professor Leonard Findlay and *Diseases of the Stomach* by Dr Hugh Morton

In the New Spanish Parliament forty seven doctors have seats

Letters, Notes, and Answers

All communications in regard to editorial matters should be addressed to **The EDITOR British Medical Journal British Medical Association House Tavistock Square W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents desiring to be supplied with reprints of their communications should notify the fact when sending them for publication

Authors desiring REPRINTS of their articles, should communicate with the *British Medical Journal* Financial Secretary and Business Manager British Medical Association House Tavistock Square W C 1 on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as all letters or copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 6661, 6662, 6663, and 6664 (ten lines)

The **TELEGRAPHIC ADDRESSES** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL* *Articulate Westcent London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc) *Articulate Westcent London*

MEDICAL SECRETARY, *Medisecra Westcent London*

The address of the Irish Office of the British Medical Association is 16 South Frederick Street Dublin (telegrams *Bacillus Dublin* telephone 7390 Dublin) and of the Scottish Office 7, Drumsheugh Gardens Edinburgh (telegrams *Associate Edinburgh* telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Prophylaxis of Lumbago

"S L" would be glad to hear of any treatment other than that which in other practitioners hands has proved of benefit in preventing lumbago He has a patient who suffers from attacks of extreme severity occurring once or twice a year when weather conditions appear to be having a bearing on the immediate cause Attacks come on with extreme sudden ness and in a few seconds the patient is helpless and cries out on the least movement For the first few days of an attack the patient cannot turn in bed cannot blow his nose and a fit of coughing would cause agony Radiant heat greatly relieves temporarily In other respects the patient is quite healthy and normal as to the condition of all organs blood pressure etc He is a tee totaller and is over 40 years of age, a business man, doing no specially arduous or out of door work

Glossitis

Dr. Thomas Jones (Colwyn Bay) writes: The condition described by "T. S. S." is probably chronic streptococcal glossitis (see *Rose and Carless*, 1930, p. 915). Treatment is as follows: avoid acids, pungent drugs, potassium bromide, chlorides, and condiments, etc.; make good use of tongue by masticating food well, swill the mouth after each meal with glyc. thymol co., diluted with fairly warm water; also wash dentures thoroughly before replacing. Should tongue become dry suck glycerin pastilles (Allen and Hanburys).

Income Tax

Motor Accident Expenses

"Exe" took over a practice in 1930, buying a second-hand car for £30. As a result of an accident he sold the car for £1, buying another for £95, and was compelled to pay further sums by way of damages and legal costs. Can he deduct these expenses?

*** In calculating his profits for his first year, "Exe" can deduct the cost of replacing his car to the extent of £30 − £1 = £29, and, in our opinion, also the legal and other costs incurred as a result of the accident. (We assume that it occurred while the car was being used for professional purposes.) But the question of the damages and costs is not free from argument, and in the event of that claim being refused by the local official we advise "Exe" to place all the facts before the authorities at Somerset House and ask for sympathetic consideration.

LETTERS, NOTES, ETC.

British Drugs

Dr. W. Bertram Watson (Harrogate) writes: The newspapers, led by the National Government, exhort us to "Buy British." May I suggest there is an additional duty on ourselves—where possible, to "Prescribe British."

Menorrhagia not due to Uterine Disease

Dr. N. Pines (London, E.) writes: May I add one remark to the valuable paper by Dr. James Young on menorrhagias not due to uterine disease, published in your issue of September 26th. Diabetes mellitus may be the cause of a sudden and alarming bleeding in a woman of post-climacteric age. I can cite one case, where a specialist thought of cancer of the body of the uterus, but further examination proved the womb to be quite healthy. A few weeks afterwards I discovered glycosuria, and put the patient on diet. Since then—more than five years ago—she has had no further haemorrhage.

Phimosis and Circumcision

Dr. Ian Jefferiss (Totnes) writes: As one who believes that the prepuce, like the tonsil, does not require mutilation, I entirely disagree with everything Dr. Jessiman says (September 19th, p. 554), except that he does not favour stretching. When no scar tissue is present, all that is required—and I have pointed this out more than once in the columns of the *Journal*—is to pass a blunt probe between the foreskin and glans, sweep it round, draw back the skin, break down adhesions, remove smegma, and immediately draw it forward. Do this three or four times at intervals of a few days; show the mother or nurse how it is done, the glans acts as the stretching agent. Habits which are said to be due to the presence of a prepuce are as common in the female, yet we do not mutilate the corresponding organ. Circumcision is a relic of barbarism and religious fanaticism. Being covered with mucous membrane (like the vagina) the glans requires protection, and intelligent parents are coming to realize that a great deal of this unnecessary interference with helpless children is quite uncalled for. To say that there is no pain during and after the absurd mutilation of the organ is simply extraordinary.

"G. F." writes: Dr. Jessiman advises "circumcision in every male child . . . even if easy retraction of the prepuce is possible." Granted an intelligent mother, surely she can be taught to retract the prepuce gradually. Is there any evidence that a penis covered by a prepuce which is retracted and washed in the child's bath can cause balanitis, convulsions, etc.?" Are the non-circumcising races of the earth more liable to convulsions and enuresis than Jews and Mohammedans? Of my three sons one was circumcised at birth and the others never. None of them suffered from enuresis, nor did I as a child, but two of my grandchildren—both circumcised—have this troublesome habit. Dr. Jessiman does not even mention the great argument in favour of circumcision—namely, the lessened liability to contracting syphilis. Do monkeys learn "bad habits" owing to lack of circumcision? If the prepuce was only evolved as a protection to the glans, why should it have nerves of special sense? No; the prepuce is a part of the genital organs.

Maggots in Wounds

Dr. Janet M. C. Gray (London, S.E.) writes: I was very much surprised to see in the *Journal* of September 19th the article on this subject. Since 1892 until the end of 1928 my work was chiefly hospital work in India, although not entirely; but it was only there that I saw wounds infested by maggots, and in every case I did my best to get rid of them. A girl Mohammedan, in a village fifty miles from a hospital, had extensive disease of her right tibia, swarming with them; the skin was all destroyed, and her foot was like a boat-full of foul fluid, and the fetor was intense. I amputated at the knee, and she made a very good recovery and went back well. I had several cases among out-patients, who had maggots in their noses and were frantic with the distress they caused; drachm doses of chloroform syringed up their noses cured them completely; once a woman fell to the ground and was unconscious for a few moments, but soon recovered. I, like all the surgeons I have met with, had a great abhorrence of fetid discharges, and carried on a constant fight against flies, mosquitos, bugs, fleas, and lice.

The Weak Heart?

Dr. Garry Simpson (Lancaster Gate, W.) writes: I have recently come across another life made miserable, and the patient become a confirmed hypochondriac, by being told he had a weak heart; this is only one of many sad cases I have met with in the last forty years. The case in point was a miserable, weedy-looking man about 30 years of age, who came to consult me about some ear trouble. He told me that he had a weak heart, and I suggested that I should examine it; this I did, and found it as sound as a bell, and told him so. After two months he called again, and there was such a change I hardly recognized the man; he told me he had put on half a stone in weight, and was feeling a new man in every way. He confessed that his life had been made miserable for some years by what his doctor had told him. Unless there is some organic disease or other strong reason, I look upon it as next door to criminal to tell a patient he has a weak heart.

Winter Time and the A.A.

On and after Sunday, October 4th, when summer time ends, the Automobile Association's road patrols will be on duty from 9 a.m. until lighting-up time. Patrols with night service outfits will patrol the roads from lighting-up time until midnight. The emergency service which is maintained at the A.A. headquarters in London (telephone, Whitehall 1200) is available to members throughout the night from 6 p.m. to 9 a.m.

Medical Golf

The second autumn meeting of the Sussex Medical (B.M.A.) Golfing Society was held on the links of the Brighton and Hove Golf Club on Sunday, September 27th. Play was against bogey, and the captain's prize, presented by Dr. A. H. Morton Palmer, for singles, was won by Mr. H. G. Downer with 2 down; Drs. Craig and Garland tied for second place with 3 down. The sweep in the afternoon four-ball competition was won by Drs. Garland and Twiston-Davies with a score of 6 up; Drs. Bonnalie and Wright, and Butcher and Raymond, tied, with a score of 3 up, for second place. There was a very disappointing entry for this meeting, the attendance representing less than 2½ per cent. of the estimated number of golfing doctors in Sussex. It is hoped that the spring meeting, which is to be held at Cooden Beach, will be better patronized. The address of the honorary secretaries is 8, Second Avenue, Hove, whence particulars of membership may be obtained.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, 53, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 199.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

279 Heredity in Paternal Tuberculosis

P. Nayrac and A. Breton (*Presse Méd.*, August 8th, 1931, p. 1181) conducted a pathological examination of the testes of eleven males, from 17 to 35 years of age, with bilateral pulmonary tuberculosis. During life there had been no sign of testicular tuberculosis, nor had there been azoospermia. The testes were removed a few minutes, at the most two hours, after death, and fixed at once with Bouin's interstitial injection ; five cases, those in which the pulmonary condition had developed slowly, showed a sclerosis of the interstitial tissue of the testes. This sclerosis is, in the opinion of the authors, inflammatory in origin, for they noted all stages between it and an interstitial orchitis with perivascular infiltration. Evidence of inflammatory change was found in nine cases. Long has shown that the injection of tuberculin into the testicular gland of a tuberculous guinea-pig causes hyperaemia, inflammatory oedema, and coagulation necrosis of spermatocytes and spermatoids, progressing in three or four weeks to atrophy of the tubules. Baitsell and Mason have reported that a similar injection of tubercle bacilli causes a rapid degeneration of the germ cells in the seminiferous tubules, and that both testes may be affected even if only one is inoculated. The authors do not consider that there is a specific reaction of the testicular gland to the toxin of tubercle, but that this is only one instance of a general reaction of the gland to toxins. Evidence of atrophy has been found in syphilis, alcoholism, pneumonia, *B. coli* infection, cancer, and abscess of the lung. The authors claim that it has been definitely established that the child of a father with pulmonary tuberculosis is born of an abnormal spermatozoon.

280 Anatoxine Prophylaxis of Diphtheria

R. Debré, G. Ramon, M. and G. Mozer, and Mlle J. Prieur (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, July 13th, 1931, p. 1246) have found that the usual method of administering the Pasteur Institute preparation of anatoxine, which contains 10 anatoxic units per c.cm.—namely, 0.5, 1, and 1.5 c.cm. at intervals of three weeks—gives 94 to 96 per cent. of negative Schick reactions. In this way 30 anatoxic units are given. The present authors, in an endeavour to obtain 100 per cent. of negatives, tried the effects of giving an additional injection of anatoxine, of increasing the interval between the injections, and of increasing the units in each dose. The desired results were obtained by the last method, a certain degree of immunity (measured by the amount of antitoxin in the serum) being also produced. Accordingly, an increase of the dosage to 1, 2, and 2 c.cm. is recommended. This method does not involve a more intense reaction or greater danger than the usual one, even in older children or in tuberculous subjects. Cathala claims an anti-typhoid as well as an anti-diphtherial immunity following the administration of three successive injections at intervals of 20 days of 1/2 c.cm. anatoxine with 1/2 c.cm. T.A.B. 1 c.cm. of each, and 2 c.cm. anatoxine respectively.

281 Sudden Death from Heart Disease in Adults

W. Munck (*Ugeskrift for Laeger*, July 30th, 1931, p. 787) has made a study of the post-mortem examinations at the University Medico-Legal Institute in Copenhagen during the past ten years. Of 242 necropsies on adults who had died a sudden, natural death, 130 were performed on persons whose death was traced to disease of the heart and aorta. These cases were classified according as the parts affected were: (1) the coronary arteries ; (2) the myocardium alone ; (3) the valves of the heart ; and (4) the aorta. There were only 28 women to 102 men in this material, and of the 74 comprising the first group, only 17 were females. The age of the patients was most frequently between 50 and 70. In the second group, in which only the myocardium was involved, there were 13 men and 2 women. In the third group, in which the valves of the heart were involved, there were even fewer, only 7 men and 1 woman, and it would seem that disease of the valves alone very seldom gives rise to sudden death. This is less rare when an endocarditis is complicated by diseases of the myocardium and coronary arteries. The average age in this group was only 48 years. In the last group, in which sudden death was traced to disease of the aorta, there were 25 men and 8 women, whose average age was only 45 years. These cases, all syphilitic, represented 26 per cent. of all the cases of sudden death from heart disease, whereas the cases in the first group (disease of the coronary arteries) accounted for about 57 per cent. of all the sudden heart deaths. The author notes that it was often very difficult, or even impossible, to obtain reliable information as to the existence of premonitory symptoms in persons who may have been living alone and have been found dead at home.

282 Arsphenamine-resistant Syphilis

There seems reason to believe that a form of syphilis which is resistant to arsphenamine is becoming increasingly common in France and Germany, though no such change is evident in the United States. T. H. Miller (*Journ. Amer. Med. Assoc.*, July 4th, 1931, p. 11) reports a case of primary syphilis which was resistant to this drug. The lesion healed after sulpharsphenamine and bismuth had been given intramuscularly ; the arsphenamine was carefully tested, and proved to be trypanocidal to a high degree. From the beginning the patient showed a vascular instability, and reacted badly to arsphenamine. Miller remarks that such resistance may be due to an alteration in the drug, to a change in the *Spirochaeta pallida*, or to some peculiarity of the host, who is generally considered to constitute the responsible etiological factor, although the mechanism of the resistance has not been determined. Arsphenamine-resistant syphilis may manifest itself in one or all of three ways: in persistence of lesions (as in the present case), in a persistently positive blood Wassermann reaction, or in the persistence of spirochaetes in the lesions while the patient is under adequate arsphenamine therapy.

283 Achlorhydria and Anaemia

D. T. Davies (*Quart. Journ. of Med.*, July, 1931, p. 447) records a study of the gastric secretion in cases of achlorhydria which shows that there are degrees of impairment, the most advanced being in primary or pernicious anaemia. Some patients, although showing achlorhydria, produce a good proteolytic secretion following stimulation with histamine. These patients usually do not suffer from any constitutional effects as the result of the minor gastric impairment. A further stage occurs in patients with a secondary anaemia ; in these there is an excessive mucus output, with diminished pepsin content, and in some cases a fixed *p*H. Achlorhydria with secondary anaemia is a distinct clinical entity. The splenic enlargement, atrophic changes in the lingual mucosa, and symptoms of anorexia and flatulence are analogous to what is found in the case of pernicious anaemia. Blood examinations, as a rule, readily establish the diagnosis. The response of these patients to iron, and the necessity for its continued administration, are suggestive of delayed, defective, alimentary absorption. Intermediate grades between the primary and secondary types are found in which both primary and secondary characters occur. In primary anaemia there is no mucus, pepsin is diminished or absent, and the *p*H is fixed. Davies suggests that the " intrinsic factor of Castle " must be a product of gastric secretion, which fails when and as pepsin fails. Those few patients who secreted some ferment required less intense liver treatment

than those who had no peptic secretion after stimulation. The deposit of squamous cells in the gastric secretion of cases of primary anaemia signifies the complete inability of that secretion to digest cells, normally shed from the oesophagus and carried down into the stomach. Examinations of the gastric secretion permit the grading of the degree of gastric failure ; cases of secondary anaemia fall into the second and third stages, those of the primary type into the fourth and final.

284 Pure Meningeal Spirochaetosis

S. Schwartz (*Thèse de Paris*, 1931, No. 192), who records seven illustrative cases in patients aged from 14 to 36, one of which is original, states that a pure meningeal spirochaetosis, due to the spirochaete of Inada and Ido, was first described in France during the war, in 1916, by S. Costa and J. Troisier, who have given their name to this syndrome. The clinical symptoms suggestive of the condition are a sudden onset, naso-labial herpes, and intense conjunctivo-ciliary congestion accompanied by a slight meningeal reaction. The disease may progress towards an uninterrupted recovery, or there may be one or more recurrences of meningeal symptoms, without a rise of temperature. The prognosis, however, is always favourable. A certain diagnosis can be made by a direct examination for the spirochaetes, inoculation of a guinea-pig, the reaction of neutralization, and the agglutination test of Martin and Pettit. It is probable that in the future a large number of cases of abortive meningitis will be found to be of spirochaetal origin.

Surgery

285 Paralytic Deformity of the Foot

L. J. Miltner (*Nat. Med. Journ. of China*, June, 1931, p. 313) describes an operation for the correction of paralytic deformity of the foot. Through a modified Kocher incision the lower fourth of the fibula is exposed and the peroneal tendons are divided. The posterior half of the fibula is cleared of muscular and fascial attachments, and is then separated from the main shaft of the bone by a longitudinal incision with an electric saw. Areas are cleared on the upper surface of the os calcis and the posterior surface of the tibia. The piece of fibula is now broken off, swung inwards, and fastened down by a screw to the tibia, the surface of which has been roughened by a chisel. After suturing the peroneal tendons the wound is closed. The fragment of fibula thus acts as a block to limit the movement upwards of the os calcis. Finally, a subastragaloid arthrodesis is performed, and the foot is put in plaster for three or four months according to the time taken for the bones to heal as observed by radiograms.

286 Deaths following Therapeutic Injections of Varicose Veins

K Kettel (*Ugeskrift for Laeger*, June 11th, 1931, p. 641) traces the rarity of embolism among patients, whose varicose veins have been treated with injections, to the gradual development of the thrombus and to its secure attachment to the wall of the vein. If a vein is excised only ten to fifteen minutes after an injection, no changes are to be seen in the intima. It does, however, show certain changes after two or three hours, and after twenty-four hours the thrombus which has formed has attached itself so securely that it can be removed from the wall of the vein only with the help of scissors and forceps. In six to seven days organization of this thrombus is in full swing. With regard to the score of deaths which have been recorded in association with this treatment, the author insists that a careful scrutiny of these records leads to the conclusion that in uncomplicated cases the risk of embolism is practically non-existent, provided that the correct technique is practised, and hypertonic salt solutions are used of so high a concentration that a violent reaction in the intima is provoked, with the consequent formation of a very adherent thrombus. The two sequels which together impose a mortality risk of from one-quarter to one-third per thousand are sepsis and the formation of a secondary coagulation thrombus proximal to the site of injection. Of the 20 deaths in the literature, 4 are discarded by the author as having been too sketchily recorded to be considered. Among the remaining 16, two were due to poisoning by mercury, which should evidently never be used, even in small doses, to this end. Three deaths were due to sepsis, and one to disease of the coronary vessels which had nothing to do with the treatment. With regard to the remaining ten deaths, all were due to embolism of the pulmonary arteries, but a causal relationship between this accident and the treatment could not always be incontrovertibly established. These 20 deaths occurred in association with about 60,000 injections. The author believes that even this small operation risk can be further reduced by never giving an injection when there is the slightest suspicion of an already existing infectious process, for an injected varicose vein is a *locus minoris resistentiae* easily subject to infection.

287 Osteochondritis Dissecans

G. Wagoner and B. N. E. Cohn (*Arch. of Surg.*, July, 1931, p. 1) describe osteochondritis dissecans as a non-infectious process involving the articular cartilage and the subchondral bone of certain long bones of the extremities, which, by sequestration from the articular surface, usually produces a single foreign body, or possibly two, in the contiguous joint. The body is of osteo-cartilaginous composition, but undergoes structural alteration by the joint fluids. The most common site is the mesial half of the articular surface of the internal femoral condyle, but the heads of the radius, femur, and humerus may be affected. The disease occurs most frequently in the tall, rapidly growing boy. The involvement by osteochondritis dissecans of more than one joint in the same person is uncommon, but when it does occur it is frequently found to be bilateral. Various etiological theories are mentioned, such as trauma, the result of static inperfection, vascular changes secondary to arthritis deformans, infarction secondary to a fat embolus, and infection. Five cases are reported which support the authors' view that heredity operates as an etiological factor in the occurrence of osteochondritis dissecans ; three were members of the same family—son, father, and paternal uncle—and the other two patients were brothers. In four instances operation for the removal of the loose body was performed with complete success.

288 The Diagnosis of Brain Abscess

I. L. Meyers (*Arch. of Otolaryngol.*, May, 1931, p. 683) records a study of twenty-four cases of abscess of the brain, which he has observed. In all the diagnosis was confirmed either by operation or by post-mortem examination. In the whole series it was found that conjugate deviation of the eyes was a most valuable sign in diagnosis. In cerebral abscess this deviation was to the side of the lesion, and was accompanied by deviation of the head to the same side ; it was extreme in lesions of the angular gyrus, of moderate extent in the Rolandic area, and absent in the frontal region. In abscess of the cerebellum conjugate deviation is always present regardless of the position of the head, and is directed to the side opposite to the lesion. Nystagmus may be slight or absent in abscess of the cerebellum ; if present it is towards the side of the lesion, if the labyrinth is functioning, and to the opposite side if the labyrinth is destroyed.

289 Prevention of Post-Operative Broncho-pneumonia

L. Cevario (*Il Policlinico*, Sez. Prat., August 3rd, 1931, p. 1105) states that the post-operative complications affecting the respiratory tract consist of tracheo-bronchitis which may become transformed into broncho-pneumonia, lobar pneumonia, or pleuro-pneumonia. These complications are most liable to develop in the cold season of the year, and the anaesthetic (especially ether) plays an important part in their production. They may occur, however, in the summer and after a local anaesthetic. They are all the more likely to arise when the operation

has been long and serious, especially if there has been previous involvement of the respiratory tract The danger is greatest during the presence of an epidemic of influenza For the last year Cevario has avoided the risk of complications by keeping the patients 24 hours before and after the operation in a room communicating with the operating theatre of the same temperature By this method he has performed urgent operations on patients the subjects of bronchitis, influenza, pleurisy, or asthma without a single failure

Therapeutics

290 Treatment of Accidental Perivascular Injections

Perivascular infiltrations may be due to various causes and the immediate and secondary reactions of the tissues to infiltration with irritating solutions are well known For infiltrations with arsenical solutions T K Lawless (*Journ Lab and Clin Med*, July, 1931, p 1019) employs sodium thiosulphate as follows One gram of the salt is dissolved in 15 c cm of sterile distilled water The arm band of a blood pressure apparatus is placed as high above the infiltration as possible, and is inflated until both the venous and arterial circulations are stopped With a needle 10 to 20 c cm of blood are withdrawn from a vein as far below the infiltration as possible, and 10 c cm of the solution slowly injected the constrictor is gradually released and the remaining 5 c cm are injected simultaneously The relief of pain is immediate and muscular spasm is equally influenced Necrosing arsphenamine lesions yield to this method in a surprisingly short time Brief notes are given of a case of a tumour caused by perivascular infiltration due to arsphenamine, both the blood and the tumour fluid being positive for arsphenamized arsenic seven months later Abelin's test for the presence of arsenic in blood is also described

291 Immunization Against Scarlet Fever

A Lichtenstein (*Acta Paediatrica* June 30th, 1931 p 539) records the results of combined active and passive immunization against scarlet fever in forty adults and forty two children who had been exposed to infection The technique was as follows Dick positive cases were first given anti scarlatinal serum, or, if they had previously received horse serum, convalescent's serum The doses of the first were 10 c cm for children, and 20 c cm for adults of the latter 25 c cm were administered to children and 50 c cm to adults Within a week active immunization was carried out using a vaccine containing 1 billion streptococci with 0 20 c cm of toxin per c mm Adults were given doses of 0 1 0 5, 1 2, and 5 c m , and children 0 1, 0 3 0 5 0 7 and 5 c cm of the vaccine The injections were made at intervals of three or four days and the results were as follows After the injection of the serum 27 of the 40 adults, and 37 of the 42 children, became negative after vaccination the Dick reaction became negative in all None of the patients contracted scarlet fever until five weeks later, when all developed the disease Six weeks after treatment the Dick reaction had become positive again in 12 out of the 21 cases examined

292 P S Rhoads (*Journ Amer Med Assoc*, July 18th, 1931, p 153) agrees that the Dick test was a reliable indication of immunity to scarlet fever, since no case developed among 533 nurses with negative reactions, whereas there were 15 cases during the same period among 449 nurses who were either Dick positive, or were neither tested nor immunized Immunization with five doses of scarlet fever toxin of 500, 2 000, 8,000, 25,000, and 80,000 skin test doses injectively was successful No scarlet fever developed among 298 nurses who received the full series of doses whereas 14 cases occurred among 449 who had had no immunizing doses and there was one case in a nurse who had had only three doses The results of immunization against diphtheria with five doses of toxin antitoxin and with diphtheria toxoid, followed by retesting and more doses when indicated, were distinctly better than when only three doses had been given

293 Hypertension and Dietetic Therapy

From a view of the literature on the relation of hypertension to cardio vascular renal change W W Priddle (*Journ Canadian Med Assoc*, July, 1931, p 5) concludes that many cases of hypertension are primarily of the so-called essential type, and that renal and vascular diseases, which were formerly considered a cause of the increased blood pressure, are really its results Stigmata of disturbance of the sympathetic nervous mechanism have frequently been noted in hypertensive patients, hence, a cause of the increased peripheral resistance of the circulation may lie in this system The sodium ion appears to be a factor in the increase of blood pressure, and the potassium ion in lowering it The restriction of sodium, calcium, and magnesium and the increase of potassium intake, in 45 cases of hypertension (here analysed) brought about uniform clinical improvement and reduction of the blood pressure Priddle considers that a knowledge of the mineral content of the food is essential for the proper treatment of hypertensive cases since this is not always easy to obtain, an outline of suitable dieting is given He believes that it will be necessary for all patients with well established hypertension to continue their diet restrictions indefinitely, and many will have to maintain permanently a high potassium intake Saline cathartics should be avoided, and also bread, butter, and cheese

294 Treatment of Amoebic Infestation

P W Brown and A E Osterberg (*Amer Journ Med Sci*, August, 1931 p 257) remark that, while emetine will probably continue to prove effective in controlling the acute phase of amoebic infestation of the intestines, it must be used in conjunction with arsenical preparations in a large percentage of cases in order to effect a cure They have therefore conducted an investigation of the clinical toxicity and rate of elimination of such organic arsenicals as stovarsol and treparsol in such patients though they believe that non arsenical remedies like yatren or dihydranol will eventually prove more popular The authors have found emetine and treparsol very satisfactory and recommend them as the first line of treatment unless contraindications to their use are present The rate and route of arsenic elimination following the administration of treparsol were determined in four cases in a group of 253 patients suffering from entamoebiasis It was found that the more finely ground preparations were absorbed more quickly and excreted more rapidly These four patients received a single course of treatment consisting of the daily ingestion of 0 75 gram of treparsol for four days Two patients chewed the tablets, and two swallowed them whole In the first two patients the ratio of arsenic in the urine to that in the faeces was 1 to 3, but when the tablet was swallowed without chewing the ratio in one patient was 1 to 9, and in the other 1 to 16 In all cases 90 per cent or more of the total arsenic was recovered by the third day following the last ingestion Treparsol seemed to be more rapidly eliminated than stovarsol, and to produce fewer untoward sequels, such as peripheral neuritis The authors emphasize the danger of continuing the administration of organic arsenicals when warnings of intolerance are present, they add that certain persons are very sensitive to arsenic in any form, toxic erythema and even exfoliative dermatitis resulting

295 Physostigmine in Exophthalmic Goitre

I Bram (*Arch Int Med*, July 1931 p 127) submits a preliminary report on the treatment of 200 cases by physostigmine salicylate none of the cases has yet been observed over a long period but the results obtained so far are thought to justify publication Digitalis even in very large doses has not given any encouraging results in the treatment of tachycardia due to thyroid intoxication except when rhythm is disturbed an mean of reducing the heart rate should save the heart from effort, and postpone or prevent the onset of failure hence the use of physostigmine in combating sympathicotonia can be considered a rational measure In 73 per cent of cases so treated there was an appreciable lowering of the rate and force of the heart beat The doses ranged from

1/30 to 1/60 grain three times a day, the larger ones being administered to patients weighing 9 stone or more; accessory measures of treatment, such as rest in bed, high caloric diets with low protein content, and hypnotics when required, were also given, and septic foci were eradicated whenever discovered. As a control 100 patients were treated on ordinary lines; it was found that improvement of the cardiac symptoms was obtained much less rapidly than with the use of physostigmine, and that periodic crises were more frequent. Results of treatment, up to the present, show that 49 per cent. of the patients have regained a normal pulse rate, and maintain the improvement of their general condition; 48 per cent. have shown transient but tangible improvement, and 27 per cent. have not been influenced. The drug had to be discontinued in 5 cases only, on account of diarrhoea. The best results were noted: towards the age limits (under 14 and above 50); in the case of patients approaching remission after one or more crises; in chronic protracted forms of exophthalmic goitre; in patients with a basal metabolic rate of less than plus 40 per cent.; in extreme exophthalmos; and in cardiac arrythmia, especially auricular fibrillation, the drug being given in combination with 5-grain doses of quinidine sulphate three times daily. The improvement in the exophthalmos was often very gratifying in chronic and stubborn cases. In a few instances of post-operative recurrence, with excessive exophthalmos, physostigmine produced particularly good results.

Disease in Childhood

296 Enuresis of Allergic Origin

G. W. Bray (*Arch. Dis. in Child.*, August, 1931, p. 251) emphasizes the fact that some cases of persistent enuresis are allergic in origin. In this condition, when there is no response to the routine therapy of waking the child, restricting the fluid intake, and administering belladonna, the application of protein skin tests may reveal the true causal factor; its subsequent elimination on the lines thus indicated, possibly combined with the administration of judicious doses of ephedrine, will probably lead to a prompt cessation of the habit. Illustrations are given of children betraying hypersensitivity to wheat, feathers, horse-hair, eggs, potatoes, pork, and other foods. When these sources of irritation were removed, recovery at once ensued. Enuresis may accompany such a condition as lichen urticatus, which is of allergic origin. It also occurs similarly with asthma, hay fever, eczema, urticaria, and migraine. Delay in diagnosis is brought about by the parents regarding the enuresis too often as a transient infantile weakness, and neglecting to obtain medical advice.

297 Pneumococcal Peritonitis

M. Lafitte (*Bull. et Mém. Soc. Nat. de Chir.*, June 13th, 1931, p. 835) reports six cases of pneumococcal peritonitis, all occurring in girls between the ages of 5 and 14. In two cases a vulvo-vaginitis was present, and in two the bacteriological examination demonstrated abundant pneumococci. Four children came from the same district, which was a very poor one, and where they had been living under bad hygienic conditions. In only one instance were the home conditions fairly good. The onset of the disease was rapid and violent, with high temperature and rapid pulse; in every case there was diarrhoea which lasted for several days. Sickness was present in most cases, and abdominal distension with rigidity was very marked. Operations were performed in five cases following a diagnosis of appendicular peritonitis in four of the patients. In three cases free pus was found in the abdomen. The appendix in each case was normal, or slightly inflamed. Of the five patients operated on two died; the remainder had a stormy convalescence with secondary infections such as pleuro-pneumonia, localized peritonitis below the umbilicus, parotitis, and metastatic abscess. The three children who recovered were in hospital for five or six weeks, but were finally restored to good health. In one instance no operative treatment was carried out, and the child died the following day. It is suggested that in all cases where pneumococcal peritonitis is suspected a laboratory examination of the vaginal discharge should be made. The question is discussed whether surgical intervention is advisable, and the author is of opinion that when a diagnosis of pneumococcal peritonitis has been confirmed by microscopical examination, medical treatment is preferable. In cases where the diagnosis is in doubt an exploratory laparotomy should be undertaken in order to examine the condition of the appendix and the abdomen generally.

298 Suppurative Arthritis in the Infant Hip-joint

C. Roederer (*Bull. et Mém. Soc. Chir. de Paris*, May, 1931, p. 254) emphasizes the importance of early diagnosis of suppurative arthritis of the hip-joint, which is often confused with congenital dislocation. The acute stage of the disease may pass unrecognized; it may lead to the destruction of the bony tissue and a dislocation which is difficult to reduce, and which after reduction may again become dislocated owing to the destruction of the ligaments. The prognosis is grave, but may be modified if early diagnosis is made with immediate surgical intervention and vaccine therapy. The result of this treatment depends on the virulence of the pathological agent, which may be pneumococcal, streptococcal, or staphylococcal, and on the condition of the joint. In certain cases excellent results have been obtained and the function of the hip has been completely restored. Sometimes, however, during the development of the child, modifications take place in the articulation of the joint which give less satisfactory end-results. A case is quoted of a child who wore an instrument to keep the leg in abduction for more than two years; when this was replaced by a celluloid splint and walking was permitted, the dislocation recurred immediately. The importance of early diagnosis and prompt treatment is stressed, and cases in which treatment was delayed are described with the bad results that ensued.

299 Intracranial Haemorrhage of the Newborn

Intracranial haemorrhage was found by R. M. Tyson and W. H. Crawford (*Amer. Journ. of Obstet. and Gynecol.*, May, 1931, p. 694) in one out of three cases of stillbirths, and also of neo-natal deaths, coming to necropsy; including the non-fatal cases, approximately one in fifty births in a series of 2,256 was associated with intracranial haemorrhage. About one infant in three recovered. The mothers included equal proportions of primiparae and multiparae, and the great majority were at term. Intracranial haemorrhage occurred in 0.8 per cent. of spontaneous labours; for cases of forceps delivery, version, breech delivery, and Caesarean section the corresponding percentages were 2.3, 7.6, 13.8, and 1.1 respectively. In the prevention of bleeding the authors attach importance to judicious cutting short, by obstetric operation, of the second stage of labour when its duration has exceeded two hours; active methods of artificial respiration should be abandoned in favour of the carbon dioxide and oxygen apparatus, or the Drinker respirator. Prophylactically, 10 c.cm. of the mother's blood may be injected into the muscles of each buttock before the infant leaves the delivery room after difficult labour. Diagnosis is dependent on the history of labour and the recognition of: (1) fretfulness, especially on manipulation; (2) difficulty in swallowing; (3) absence of the suction reflex when the nipple is placed in the mouth; (4) cyanotic spells, which may be provoked by disturbance; and (5) muscular twitchings or convulsions. Lumbar or cisternal puncture gives vent to a fluid which almost invariably contains blood and under a pressure increased from a normal average of 8 mm. to averages of 11.5 and 15.7 mm. in non-fatal and fatal cases respectively. Cerebro-spinal fluid containing blood is found, however, in about one in five normal infants. In the treatment repeated drainage of the spinal fluid is invaluable; careful nursing is required, and bathing and dressing may have to be omitted for a time.

Obstetrics and Gynaecology

300 Anaemia of Pregnancy

S. Mitra (*Indian Medical Gazette*, July, 1931, p. 363) gives an account of the anaemia of pregnancy—the "puerperal chlorosis" of Lebret—found in India. Although this disease is rare in the United Kingdom and on the Continent, it is common in India. Among 1,883 cases delivered at the Women's Hospital, Calcutta, there were 86 of anaemia during the last four years. A complete analysis of these cases is given. This aplastic anaemia differs from pernicious anaemia: (1) in being always associated with pregnancy and terminating with it; (2) in the absence of marked remissions and exacerbations; (3) in its shorter duration; and (4) in occurring at a comparatively younger age. According to the graphs given in the text the anaemia of pregnancy develops most commonly about the twenty-fifth year, and after the sixth month of pregnancy. It appears to be more frequent in the later months of the year. The clinical course is very rapid, the patient being either dead or cured in the average of 11.4 days. The blood picture shows an average of 28.4 per cent. haemoglobin; 1.35 colour index; a red blood count below one million in 40 per cent., and under two millions in 53.7 per cent. of cases; no leucopenia; and the presence of myelocytes, anisocytes, and poikilocytes. In 9 out of 10 cases premature labour occurs spontaneously; the maternal and foetal mortality rates are very high. Definite histological changes are found in the liver, which appear to point to a toxaemia of pregnancy. With regard to treatment, symptomatic and palliative measures were employed until the pregnancy was terminated. Blood transfusion and many other therapeutic measures were tried. In order to stimulate the activity of the reticulo-endothelial apparatus, fractional deep *x*-ray doses were delivered over the liver, spleen, and heads of the long bones in 16 cases. The results of this treatment were encouraging.

301 Choline in Treatment of Menopausal Symptoms

K. Adel (*Zentralbl. f. Gynäk.*, June 6th, 1931, p. 1843) quotes reports in which it is stated that the choline content of the blood, normally from 1.5 to 2 mg. per cent., is increased in menstruating women by six to eight times, and that during the menses the choline of the sweat is increased nearly a hundredfold. Choline is present in the organism in the form of esters, which are much more active physiologically than choline. They stimulate the parasympathetic system, and antagonize adrenaline, thus inducing diminution of blood pressure, and the dilatation of arterioles, veins, and capillaries. Choline is unsuitable for oral administration, being hygroscopic; acetyl-choline, besides requiring parenteral injection, is too active for therapeutical convenience. Abel, in an extensive series of tests, has had, like other German observers, very satisfactory results from the use of a double choline ester in the treatment of functional symptoms of the menopause. Success is chiefly attributed to correction of the irregularities of the vasomotor system to which flushings, rushings of blood to the head, headache, and insomnia are due.

302 Serum Prophylaxis of Puerperal Fever

A. Schossberger (*Zentralbl. f. Gynäk.*, July 4th, 1931, p. 2125) states that in every case of delivery in which a vaginal examination has been made, or any internal or external trauma has occurred, he has given a prophylactic intramuscular injection of a polyvalent streptococcal serum immediately after birth and before the delivery of the placenta. Of 100 cases so treated, including Caesarean section, forceps cases, versions, and cervical and perineal lacerations, the results have been remarkably good. During the first five days after delivery the axillary temperature never exceeded 99°, and subsequently there were only slight rises of temperature, partly due to the condition of the breasts, and partly to serum sickness. Schossberger concludes that not only the mortality but also the morbidity of puerperal fever can be reduced to nil both in hospital and in private practice. He thinks that serum prophylaxis should be made compulsory in all deliveries, just as is Credé's treatment of the eyes of the newborn; this is especially important when the delivery is not being conducted in a large lying-in institution.

303 Salt-free Dieting during Pregnancy

J. Hofstein and P. S. Pétrequin (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, May, 1931, p. 390) have noted in four cases that patients who had been given diets free from salt some weeks before term had rapid and easy labours. In order to ascertain whether this was merely coincidental, or if the special diet had any influence on labour, determinations of the blood chlorine figure and alkaline reserve were made in 18 cases. These showed that there was no apparent relation between the amount of chloraemia and the progress of labour; the chlorine was usually normal and the alkaline reserve lowered. A strictly salt-free diet was then given to six primiparae some weeks before term; in these labour was easy with only little pain, and the period of dilatation was short and uneventful. Though this series of cases is small, the authors consider that the results merit further investigations along this line.

304 Differential Diagnosis of Ovarian Haemorrhage

A. Als-Nielsen (*Ugeskrift for Laeger*, July 2nd, 1931, p. 703) has found that in the Surgical Department D of the Bispebjaerg Hospital in Denmark as many as 14 cases of pathological ovarian haemorrhage came to operation in the course of the last three years. At one time ovarian pregnancy was considered the only cause of pathological ovarian haemorrhage, and as late as 1916 Forssner insisted that all the cases hitherto recorded of haemorrhage from ruptured corpora lutea were really due to ovarian pregnancy. Before this diagnosis could be eliminated, serial microscopical sections would have to be made with a negative result. Several subsequent studies have, however, invalidated this hypothesis, and the author traces none of his cases to pregnancy, although in several he did not examine the ovaries microscopically. He could not do so, as the treatment was limited in some instances to cauterization of the bleeding point. In as many as five cases, small cystic degeneration of the ovary was observed, and in six cases (including several of the above five) the haemorrhage was probably due to rupture of a follicular cyst. With regard to the pre-operative diagnosis, the author finds from a study of the literature that the true state of affairs is never diagnosed before operation; the large haemorrhages are traced to extrauterine pregnancies, the small haemorrhages to appendicitis or salpingitis. In the differential diagnosis between this condition and appendicitis two factors may be helpful: the coincidence of the symptoms with the period of ovulation, and the suddenness of the onset of the symptoms. With only two exceptions, the patients in the author's material described the pain as having begun quite suddenly, having been violent, and as having passed off quickly—a series of happenings to be explained on the assumption that they coincided with tension and rupture in the ovary, followed by the effusion of blood causing more or less marked irritation of the peritoneum which passes off after a time. Apart from these two points, the author can find nothing wherewith to clarify the differential diagnosis.

305 Abscess of the Pregnant Uterus

R. L. Wood (*New York State Journ. Med.*, June 15th, 1931, p. 747) reports a case of an abscess in a pregnant uterus; rupture occurred into the peritoneal cavity, but the patient recovered. After spontaneous rupture of the membranes in the course of an apparently normal confinement a child was born, and the placenta came away spontaneously ten minutes later with only slight bleeding. Half an hour afterwards the patient had intense pain in the right lower abdominal quadrant; the systolic pressure fell to 60, the red cells numbered only just over 2 millions per c.mm., and the pulse became imperceptible. After blood transfusion the abdomen was opened, and free pus exuded. On the posterior uterine surface, just below the

right cornu, and behind the round ligament, there was a ruptured abscess cavity as large as a walnut ; it did not communicate with the cavity of the uterus. Suction drainage was instituted, and the abdomen was partly closed. Rectal instillations of saline solution and the adoption of Fowler's position, with the exhibition of digifoline, were followed by recovery. Wood concludes that the cause of the abscess was a small fibroid, which had undergone degeneration, with progressive thinning of the wall over it. With the first hard uterine contraction it had ruptured, the consequent shock nearly proving fatal.

Pathology

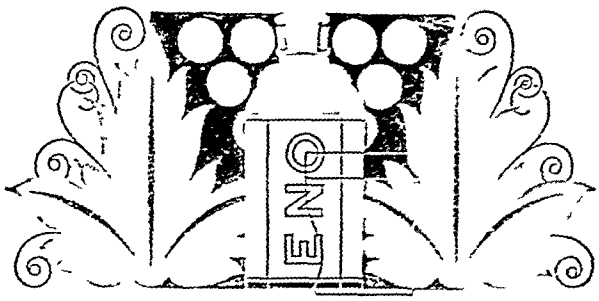
306 The Renal Function in Diphtheria

R. Lereboullet, J. J. Gournay, and J. Donato (*Ann. de Méd.*, May, 1931, p. 547) record their observations on 60 cases of diphtheria in which they had estimated the blood urea concurrently with determining the glycaemia and cholesterinaemia ; 20 of the cases were ordinary, and 40 malignant attacks. They also made a chemical and microscopical examination of the urine, measured the urinary output, and in some cases tested the renal permeability by the usual methods. Their results were as follows. In mild forms of diphtheria the blood urea was normal or only slightly modified, ranging from 0.25 gram to 0.40 gram per mille. Among 20 fatal cases of malignant diphtheria with symptoms of suprarenal insufficiency there was an initial and terminal increase in the blood urea in 16. Clinical as well as anatomical and experimental data did not indicate any severe renal involvement in most of the cases of diphtheria, and on microscopical examination of the kidneys of children who had died from malignant diphtheria, or in animals killed by diphtheria toxin, no very marked lesions of nephritis were found. Subsequent examination of diphtheria convalescents, who had had nephritis during the acute attack, showed that the kidneys were normal. The authors conclude that while the kidney may be affected like the other organs with severe diphtheria, and its involvement may be accompanied by well-marked azotaemia, it is rarely a predominant feature, the cardiac, suprarenal, and nervous involvement being much more important.

307 Anti-coagulant Action of Uroselectan

G. Ravasini (*Biochim. e. Terap. Speriment.*, May 31st, 1931, p. 141) has studied the action of uroselectan—iodo-piridon acetate of sodium—in delaying or inhibiting the coagulation of the blood of normal rabbits. This was first demonstrated *in vitro* by adding increasing doses of uroselectan to 5 c.cm. of blood drawn from the carotid, and observing the interval of time between the termination of the bleeding and the loss of mobility of the blood in the test tubes. *In vivo* experiments comprised intravenous injections of increasing doses of a 30 per cent. solution of uroselectan, and after 90 seconds collecting the blood and noting the appearance of coagulation. It was found that in a rabbit after receiving 1.25 grams of uroselectan per kilo of body weight, coagulation of the blood occurred twenty minutes after the bleeding—as compared with the normal eighteen minutes. In a rabbit that had received 2 5 grams per kilo, coagulation did not ensue until after six hours; the blood of rabbits injected with 5, 7.5, 10, 13, 16, and 19 grams per kilo remained liquid for twenty-four hours after bleeding.

308 Detection of Occult Haemoglobin in the Faeces



I. Boas (*Deut. med. Woch.*, July 24th, 1931, p. 1271) describes a method for detecting haemoglobin (as distinct from haematin) in faeces. After three to four days of a diet containing no fish, meat, or chlorophyll, 3 to 5 grams of faeces are extracted repeatedly with pure acetone until the last fraction remains practically colourless after half an hour's contact. The acetone is removed as completely as possible ; the residue is dried, preferably at 37°–40° C., and ground to a fine powder. This is now extracted with 10 to 20 c.cm. of 25 per cent. alcohol, which dissolves the haemoglobin, but not the haematin ; this process is repeated until the filtrate is clear. To 2 to 3 c.cm. of the filtrate 10 drops of glacial acetic acid and 5 c.cm. of neutral ether are added ; after shaking, the guaiac or benzidine test is performed on the ether extract. The haematin can be estimated similarly by examining the residue from the alcohol extraction. In cases of insufficient gastric acidity, or increased intestinal peristalsis, haemoglobin is imperfectly reduced to haematin. The oral administration of haemoglobin, and the subsequent examination of the faeces may therefore prove to be a useful test of these conditions. In large haemorrhages from the upper or lower parts of the alimentary tract, free haemoglobin appears in the faeces, but only temporarily, for within a week or two haematin only is found. On the other hand, the repeated minute haemorrhages from ulcerating malignant disease are characterized by the persistence of haemoglobin in the faeces. Thus the presence of haemoglobin on repeated examinations is highly suggestive of carcinoma of the stomach or colon, whereas if haematin only is present, the cause is more probably simple ulceration.

309 Outbreaks of Food Poisoning due to Salmonella Infection

J. C. Geiger and Margaret Nelson (*Pub. Health Reports*, July 3rd, 1931, p. 1565) describe three outbreaks of food poisoning in which three different members of the Salmonella group were involved. The first outbreak affected 35 persons, and was due to the consumption of a creamed chicken-veal mixture. The causative organism, *Bact. enteritidis*, was isolated from the food, and it is probable that the veal came from an infected calf. In the second outbreak, which occurred in a hospital, over 200 persons were affected. Rice pudding was found to be responsible, and *Bact. aertrycke* was isolated from it directly. This organism had probably gained access to the food from rat virus poison, which had apparently been used in the kitchen two days previously. The third outbreak likewise occurred in a hospital, and involved 52 persons. An egg soufflé shrimp mixture, which had been kept standing overnight, was incriminated. Since all of this had been consumed, no bacteriological examination could be made. It was found, however, that the assistant chef was a *paratyphosus* A carrier, who had just joined the staff, and it was concluded that the outbreak was due to this organism, though it was not isolated from the stools of three patients which were examined, nor from the viscera of one patient who died. The organisms isolated from the first two outbreaks proved fatal to mice, when fed in pure culture ; the toxicity was retained, at any rate to some extent, even after heating to 240° F. for ten minutes.

310 The Congo Red Test in Pulmonary Tuberculosis

M. Lucacer and G. Cardinale (*Rif. Med.*, July 22nd, 1931, p. 951) have tried the Congo red test in 92 cases of pulmonary tuberculosis. According to Adler and Reimann, after the injection of 10 c.cm. of a 1 per cent. solution of Congo red, part of the dye is fixed by the cells of the reticulo-endothelial system ; the amount which is found in the blood one hour after the injection is the measure of the power of the reticulo-endothelial system to fix the dye. Wedekin and Löwenstein suggested that the test might be used in the diagnosis of pulmonary tuberculosis ; they estimated colorimetrically the amount of dye in the blood one hour after the intravenous injection, taking the amount present in the blood four minutes after the injection as 100 per cent. They concluded that the results so obtained gave some indication of the extension of the pulmonary lesion. Lucacer and Cardinale have now obtained results which agreed closely with those obtained by Wedekin and Löwenstein. In 24 early cases of pulmonary tuberculosis the amount of Congo red found in the blood 60 minutes after the injection ranged from 50 to 69 per cent. ; in 21 mixed cases from 53 to 78 per cent. ; and in 47 exudative cases from 75 to 95, the percentage falling between 85 to 90 in the majority of the cases.

PURGATIVES AND MALNUTRITION

The dangers attending the administration of irritant purgatives to delicate and debilitated patients have long been recognised.

Whilst a certain amount of immediate relief may be thus obtained, the disturbing effect on the autonomic nervous system and the malnutrition resulting from irritation of the absorptive mechanism frequently outweigh the temporary alleviation. There appears, also, to be considerable risk of malnutrition in the constant use of laxatives of the so-called lubricating type. The covering of the mucous membrane of the intestines with a thin coating of oil can hardly fail to lessen the absorption of aliment. Moreover, it was found by Channon and Collinson that a portion of the mineral oil is liable to be absorbed and to accumulate in the liver. The pathological possibilities of such accumulation need no stressing.

For the relief of moderate degrees of constipation, in cases in which the fullest nutrition is important, no safer or more reliable laxative can be found than an effervescent preparation of the standard of Eno's "Fruit Salt."

In Eno's "Fruit Salt," it is claimed, we have at our disposal a carefully compounded, pure and standardised preparation, entirely free from the harsh and disagreeable sulphates of soda and magnesia. Eno's "Fruit Salt" has been used and prescribed by thousands of doctors for over half a century, during which time its reputation has become world-wide.

ENO'S "FRUIT SALT"

"Urgent Abdominal Diagnostics"

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

"VARIBAN" ELASTIC PLASTER BANDAGE

SUPPLIED IN WIDTHS

2"	2½"	3"
1/5	1/7	1/9

EACH.

When stretched measures six yards (approximately).

Made from a specially woven selvedge material, possessing very elastic properties. Evenly spread with Antiseptic Zinc Oxide Paste. Self-adhesive. Will not crease or slip. Unusually firm, yet easy to remove. Extensively used in well-known hospitals for treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL AND ORTHOPAEDIC CASES, Strains, Fractures, etc.

* * *

"CELLANBAND" PASTE BANDAGES

in the Treatment of

VARICOSE ULCERATION

PHLEBITIS etc.

The "Cellanband" Dressing, when properly applied, furnishes a mechanical support, in many ways superior to crepe or rubber bandages. Soon enables the convalescent to resume light duties.

Antiseptic Paste-impregnated and, by virtue of this, "Cellanband" Dressings exercise a marked dehydrating and anti-phlogistic effect, resulting in rapid reduction of oedema. Air-access to tissue is not interfered with as in the case of Gelatine dressings.

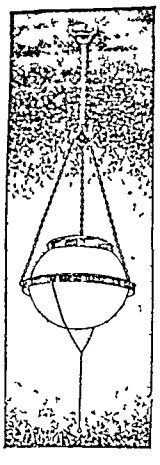
EFFICIENT TRUSSES BY POST

In many instances the Medical Man is faced with the impossibility of sending his patient to a skilled Truss Manufacturer on the grounds of ill-health, absence from employment, or cost of travelling.



Saltair Surgical Service has overcome this difficulty by fitting a patient with an **"Efficient Truss"** to his own doctor's prescription.

The special order forms we supply give us sufficient information, even in difficult or abnormal cases, to supply a spring of correct strength and shape, to cover and pad it as required, and to fit an adjustable pad of the correct size and shape. Hence, we supply, **by post**, to the doctor, a truss which is an accurate interpretation of his prescription.

THE VITREOSIL SUNSHINE LAMP

This is a powerful unit which gives a safe light equivalent in its effects and the spectrum of which is similar in range to natural sunshine. The lamp is particularly suitable for the lighting of convalescent or maternity institutions, public baths, gymnasia and welfare centres. The visible light is strong but diffused, and closely approximates in colour to daylight.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sound from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

Is it fair to your best friend to make him your Executor? The duties are onerous, and usually thankless; the responsibilities are great and the penalties for neglect are severe. Moreover, he may die, and the expense of appointing his successor is considerable. On the other hand, if you appoint the Westminster Bank instead, the fees (which are paid out of your estate) will probably be only a fraction of the legacy which you would have left to a private trustee.

Ask for the 'Executor and Trustee' booklet at any local branch, or call at

THE DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.
The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

The toxic amino-acids present in the system as the result of non-regular and imperfect evacuation give rise to rheumatism and other kindred complaints. Sal Hepatica swiftly and painlessly stimulates to peristaltic activity, ensuring complete and satisfactory elimination of all systemic poisons and waste products. Sal Hepatica induces a free biliary flow; hence its regular usage does not lead to a condition of tolerance. Sal Hepatica alkalizes the system and reduces blood pressure and as a result promptly relieves pain and distress in rheumatic conditions.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in effervescent medium.

Doctor offers Home to a few LITTLE GIRLS of age 6 to 14 years. Large airy House. Every comfort. Terms £120 per annum. Excellent references. Large garden. Private lessons if desired.—Write, 6169, B.M.A. House, Tavistock Sq., W.C.1.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary *patients*, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received *for treatment*. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients *can be admitted*. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. *There is an Operating Theatre*, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. *Milk, meat, fruit*, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and *patients are given every facility* for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of *St Andrew's Hospital* is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast *forms the boundary*. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there *are cricket grounds*, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for *handicrafts*, such as carpentry, etc.

For terms and further *particulars apply to the* Medical Superintendent (Telephone No. 56, Northampton) who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

Phone: 11 Ashton-in-Makerfield

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental *condition*.

Situated in park and grounds of *400 acres*. *Self*-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

"ITS WEIGHT AT BIRTH WAS ONLY 4 lbs."

July 9th, 1931

Dear Sirs,

The following case will, I am sure, interest you. Baby Lowe was born on November 4th, 1929, at the 28th week. Its weight at birth was 4 lbs. It was put in an incubator and fed with a fountain-pen filler. First it was fed from the breast, then on a spray-process dried milk, and finally on a peptonised food.

It was brought to the Motherhood Bureau on June 10th, 1930—aged 7 months. Its weight was 8¼ lbs. It was still fed on peptonised feeds and could take only 4 feeds a day, and vomited after these; and was therefore losing weight.

Baby Lowe was put on a Lacidac Half Cream—4 measures to 6 ozs. of water—with Mead's Dextri Maltose No. 1, 4-hourly feeds. Within a week the sickness had improved, the baby had begun to gain a little weight, and by July 10th its weight was 9 lbs. It was then put on Full Cream Lacidac and the appropriate additions of Brestol. In August Cow & Gate Rusks were added to the diet, and mixed feeding was commenced as the teeth were beginning to erupt.

In the 5 months from July 11th, 1930, to January 7th, 1931, the child gained 8 lbs., and at the last report on May 28th, 1931, was very bonny and well and was walking and climbing everywhere.

C.M.B.

Cow & Gate Milk Food

The makers will be pleased to send clinical samples of Lacidac, which is made in three strengths—full, half and separated—and Brestol to any members of the profession who may be interested

ELASTOPLAST SPECIALITIES

EFFICIENT
TIME-SAVING
ECONOMICAL

Manufactured only by
T. J. SMITH & NEPHEW LIMITED
HULL MANCHESTER
LONDON GLASGOW

Enquiries to Dept. B: 42, Tavistock Sq., London, W.C.1. Obtainable through all Surgical Supply Houses.

Elastoplast is the only elastic plaster bandage with the correct degree of elasticity to ensure perfect compression and support.

Order from your usual supplier or send P.O. value 2/6 for one introductory trial set (Overseas postage extra) to the manufacturers.

ELASTOPLAST BANDAGES
the proved cure for Varicose Ulcer, also ideal for all surgical and orthopaedic work, for Varicose Veins, Sprains, Strains, Dislocations, after-treatment of fractures, etc.

ELASTOPLAST DRESSINGS
combine medicated gauze and lint pads with the elastic plaster base, providing speedy and efficient dressings for cuts, wounds, incisions, boils, etc.

VISCOPASTE BANDAGES
(Unna Paste Type). A valuable adjunct to the after-treatment of Varicose Ulcer.

CELLONA P.O.P. BANDAGES
The new rigid P.O.P. dressing. Cleaner, easier to apply and remove, and 50% lighter than ordinary P.O.P.

SEMIPLAST
A novel form of Elastic Plaster. Any special lotion can be applied to the limb, as only the first turn of plaster comes into contact with the skin.

THE MOST EFFECTIVE TREATMENT IN PNEUMONIA — INFLUENZA CORYZA

is provided by

EDWENIL

The Original Polyvalent Antibody.

A typical pneumonia report states:

"Male adult, admitted to hospital on the second day of illness, suffering from double lobar pneumonia. His condition appeared hopeless. He was very deeply cyanosed, pulse 140, respiration 48, temperature 103·2°.

"2 c.c. of Edwenil were given, followed by a fall in temperature to 99° in 12 hours. A second dose of 2 c.c. was given. Temperature rose to 102·4 and fell again in another 12 hours.

"This cycle was repeated and temperature reached normal on the 6th day. Six hours after the first injection, it was obvious that he was more comfortable. The cyanosis began to subside on the second day. From that time improvement was rapid and uneventful."

A sufficient quantity of EDWENIL, to demonstrate its activity in your own practice, will be sent without charge. Write or telegraph

GOOD BOOKS

SAUNDERS

9, HENRIETTA ST., LONDON, W.C.2

GOOD BOOKS

Todd & Sanford's
Clinical Diagnosis

"A book which is of particular value to the student for the number and the excellence of the illustrations, the clarity of the language, and the short, but concise, notes on the indications for the applications of various tests and the interpretation of the results."—LANCET.

By JAMES CAMPBELL TODD, M.D., University of Colorado, and ARTHUR HAWLEY SANFORD, M.D., University of Minnesota (The Mayo Foundation). Octavo of 765 pages, with 500 illustrations, 51 in colours. New (Seventh) Edition. Just Issued. Cloth, 28s. net.

Jordan's
General Bacteriology

"One of the best balanced and scholarly of the current text books upon bacteriology, and has the additional charm of viewing the subject widely."—LANCET.

By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology at the University of Chicago. Octavo of 819 pages, illustrated. New (Tenth) Edition. Just Issued. Cloth, 28s. net.

Boyd's
Surgical Pathology

"This admirable work . . . meets, as no other book on surgical pathology does, the wants of those studying for the higher surgical qualifications."—EDINBURGH MEDICAL JOURNAL.

By WILLIAM BOYD, M.D., M.R.C.P.Ed., F.R.S. Can., Professor of Pathology, University of Manitoba. Octavo of 933 pages, with 476 illustrations, and 15 coloured plates. Second Edition. Cloth, 48s. net.

Ranson's
Anatomy of Nervous System

"Provides a useful foundation in macroscopical and microscopical anatomy . . . Is wonderfully complete and should prove highly serviceable."—LANCET.

By STEPHEN W. RANSON, M.D., Professor of Neurology, North-Western University Medical School, Chicago. Octavo of 480 pages, with 341 illustrations, some in colours. Fourth (Revised) Edition. Cloth, 32s. 6d. net.

Herrick's
Introduction to Neurology

"One of the most interesting books of its kind, and is easy to read because of the association of anatomy with development and function in a very attractive way."—IRISH JOURNAL OF MED. SCIENCE.

By C. JUDSON HERRICK, Ph.D., Professor of Neurology in the University of Chicago. 12mo of 417 pages, illustrated. New (Fifth) Edition. Just Issued. Cloth, 12s. 6d. net.

MacCallum's
Text-Book of Pathology

No doubt this book has often been taken down from the laboratory shelf to verify some small point, not to be replaced unremediately the information sought has been obtained; it is apt to beguile the reader, enticing him to some stimulating thought. It teaches ideas rather than facts."—BRITISH MEDICAL JOURNAL.

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University. Octavo of 1177 pages, 606 original illustrations, 50 in colours. Fourth Edition. Cloth, 45s. net.

Stevens'
Practice of Medicine

Possesses a character of its own that makes it an excellent student's and practitioner's text book."
—SOUTH AFRICAN MEDICAL JOURNAL.

By A. A. STEVENS, M.D., Professor of Applied Therapeutics, University of Pennsylvania. Octavo of 1,150 pages, illustrated. New (Third) Edition. Just Issued. Cloth, 35s. net.

Cecil's
Text-Book of Medicine

"This book maintains a very high level throughout its pages . . . Great care has been taken with the dovetailing together of the various contributions into a compact whole, and the book is a worthy production of the modern American school of medicine."
—LANCET.

Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell Medical School. Octavo of 1,592 pages, illustrated. Second Edition, Reset. Cloth, 40s. net.

Arey's
Developmental Anatomy

Professor Arey is to be congratulated on the production of a text book of embryology which may be highly recommended and is likely to be used very widely."—BRITISH MEDICAL JOURNAL.

By LESLIE BRAINERD AREY, Robert Laughlin Rea Professor of Anatomy, Northwestern University Medical School. Large octavo of 560 pages, with 1,037 illustrations on 532 figures. New (Second) Edition. Cloth, 27s. 6d. net.

McLester's
Nutrition and Diet

"Provides an excellent and well balanced exposition of the subject of Dietetics. In it justice is done to both the theoretical and practical aspects of nutrition and its value as a work of reference is enhanced by the carefully selected bibliographies presented at the end of each chapter."—EDINBURGH MEDICAL JOURNAL.

By JAMES S. McLESTER, M.D., Professor of Medicine at the University of Alabama. New (Second) Edition. Octavo of 891 pages. Cloth, 36s. net.

Pearl's
Medical Biometry and Statistics

"An excellent introductory text book. . . . likely to be of considerable service to students of medical problems."—BRIT. MED. JOURN.

By RAYMOND PEARL, Professor of Biology in the Medical School of Johns Hopkins University. Octavo of 459 pages, illustrated. Second Edition, thoroughly revised. Cloth, 25s. net.

Howell's
Text-Book of Physiology

"The author has succeeded in making his subject matter interesting and in many parts fascinating—an art deplorably rare in physiological writings. The book inspires respect rather than criticism."—EDINBURGH MEDICAL JOURNAL.

By WILLIAM H. HOWELL, M.D., Ph.D., Professor of Physiology, Johns Hopkins University, Baltimore. Octavo of 1,099 pages, illustrated. Eleventh Edition. Cloth, 30s. net.

Da Costa's
Modern Surgery

"Can be warmly recommended, not only to the student and to the practitioner, but also to the general surgeon."
—EDINBURGH MEDICAL JOURNAL.

By J. CHALMERS DA COSTA, M.D., Professor of Surgery, Jefferson Medical College, Philadelphia. Tenth Edition, Just Issued. Octavo of 1,404 pages, with 1,050 illustrations, some in colours. Cloth, 45s. net.

Dorland's
Illustrated Medical Dictionary

"The dictionary has received the most thorough revision of its long career, and several thousand terms noted in the most recent medical literature have been added. . . . It may be said that the new edition fully portrays the great amount of work that has evidently been devoted to its preparation."—BRIT. MED. JOURN.

By W. A. NEWMAN DORLAND, A.M., M.D., Member of the Committee on Nomenclature and Classification of Diseases of the American Medical Association. Octavo of 1,427 pages, with 525 illustrations, 165 in colours. Flexible binding, 35s. net, with Thumb Index, 37s. 6d. net.

LEWIS'S PUBLICATIONS

THE LONDON MEDICAL EXHIBITION

will be held in the

NEW HALL

of the

ROYAL HORTICULTURAL SOCIETY,
WESTMINSTER, LONDON, S.W.

OCTOBER
19 to 23
1931

12 noon to 6.30 p.m. Daily.

The Exhibition this year will be found of more than usual interest. A number of new medicinal substances and preparations, surgical instruments and medical appliances, will be on view for the first time in this country.

A spacious and well fitted Reception Room overlooks the Exhibition Hall, and here an orchestra will perform each day and visitors will be entertained to afternoon tea.

Invitation cards will be sent to every member of the Profession residing in London and in Counties adjacent thereto. Practitioners desiring to visit the Exhibition, who do not receive cards, can obtain same on application to the Secretary, the London Medical Exhibition, 194-200, Bishopsgate, London, E.C.2, or at the Hall during the Exhibition week.

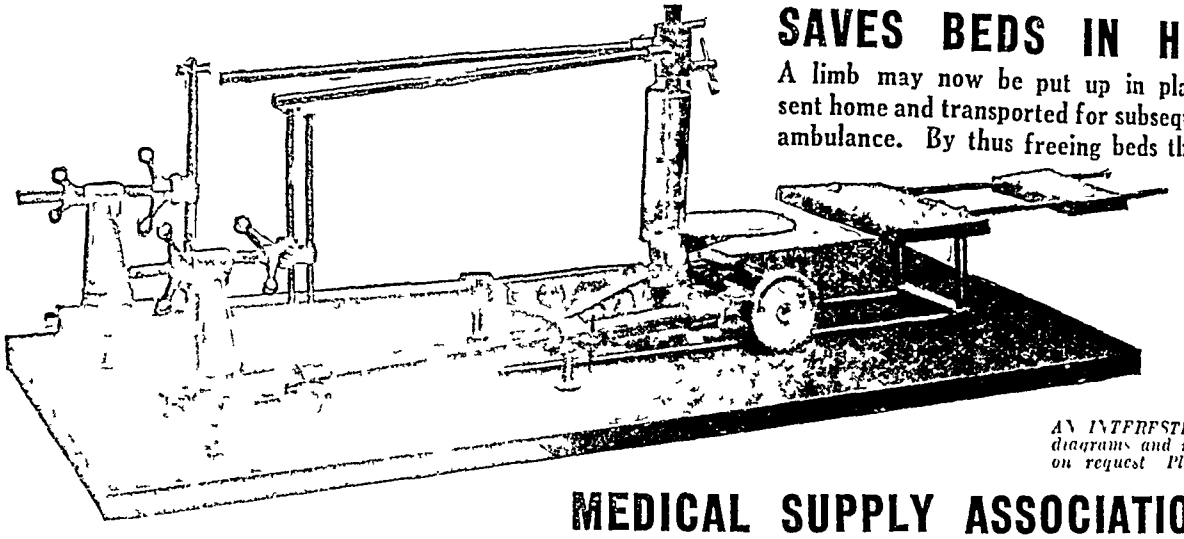
PAR EXCELLENCE



An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk, also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions

Extension of whole lower limbs
Movements about hip joint
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint
Inversion and Eversion of foot

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35in X 15in X 11in

AUTHORITIES ENDORSE ALUMINIUM *for* HYGIENIC COOKING

Public approval of aluminium domestic ware carries the full endorsement of recognised investigating authorities. The concensus of scientific opinion, British, American, and Continental, is solidly in favour of the metal.

4 GERMAN (continued).

Dr C Massatsch, *Public Analyst, Berlin. Findings published in June, 1929.* "The amounts of aluminium lost in cooking various classes of food were estimated, these were so small that they could not be determined by loss of weight, but their presence in the cooked food was shown (not quantitatively). Dogs and rats were fed with diets containing respectively aluminium oxid and dry and freshly precipitated hydrate in differing concentrations in amounts containing up to a maximum dose equivalent to 0·1326 grams alum per dog daily, no appreciable effect could be noticed."

Dr V Thieme, (*vide* Chemiker Zeitung, 18/12/29) reviewed the work done by Dr Massatsch and his co-workers. He concluded that aluminium cooking utensils were quite unexceptionable both from the technical and hygienic points of view. "No appreciable quantities of aluminium are taken up by the food, so that, apart from the unnecessariness of aluminium compounds in general, no bad effects to the health can be expected."

A résumé of medical evidence will be sent gratis on request.

IN HÆMORRHOIDS

Pruritus or Itching ★ THE MUCOUS SECRETION from the surface of hæmorrhoids, rubbed into the anal and perineal skin, causes pruritus or itching. This may be the first sign of the presence of hæmorrhoids.

ANUSOL BRAND HÆMORRHOIDAL SUPPOSITORIES quickly remedy this condition. By reducing congestion and by a slight styptic action, the mucous secretion is checked and the pruritus disappears. Simultaneously, the irritated surfaces are soothed and protected, and if the hæmorrhoidal condition has not passed the incipient stage, spontaneous recovery is still possible.

THE EFFECT of Anusol Brand Suppositories is obtained without an opiate or a local anæsthetic, which constipates, dulls sensation and obscures the symptoms.

PRURITUS is sufficiently distressful to demand immediate relief. That is why the treatment should begin at the doctor's consulting room. Let us send you a trial supply for use immediately after examination.

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne, no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete clinical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.
Works: KING'S LANGLEY, HERTFORDSHIRE.

M 230

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

'Alasil' completely overcomes this objection. By combining calcium acetyl salicylate with 'Alocol,' unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium) which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. 'Alasil' is therefore a triumph over acetyl salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

Alasil

M 233

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

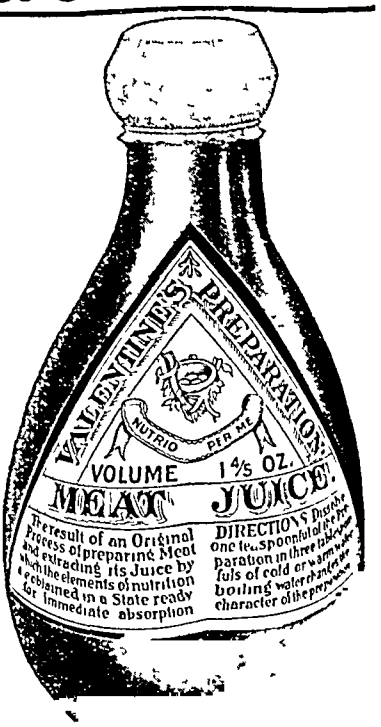
DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.



DINNEFORD & Co. LTD.

Valentine's Meat-Juice

Roboleine

THE FOOD THAT BUILDS THE BODY

A POWERFUL reconstructive food that can be administered in all conditions, even those in which ordinary concentrated feeding and tonics are not supported, must fill an important place in therapeutics. Such a product is found in "Roboleine," which has been before the Medical Profession for nearly 25 years.

Bone-Marrow in Anaemia from Haemorrhage.

W. Borchardt (Deut. med. Woch., March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib-marrow, others with marrow from the long bones. Control animals received a corresponding amount of cither fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.) Only the animals receiving the red rib marrow showed a definite increase in weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1·4 mg. per cent. The result was similar but more striking, the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others.

—*Vide* B.M.J., May 3rd, 1930.

"ROBOLEINE" contains the Marrow from the long bones, the RED MARROW OR JUICE FROM RIB BONES OF OXEN, together with Egg Yolk and a specially prepared Extract of Malt.

This is the original formula, and it may be of interest to note how closely it conformed to the latest requirements of modern research. This formula, however, has been developed in the light of clinical experience, and the vitamin content has been reinforced by the addition of our "Vitad," which is the unsaponifiable fraction of Cod Liver Oil.

ROBOLEINE may be taken by itself, or mixed with water, milk, porridge, or tea, and spread on dry biscuit forms a nourishing and stimulating "snack" lunch for children or adults.

INDICATIONS:—Rickets, Phthisis, Anaemia, Leukemia, Lymphadenoma, etc., and in those cases in which a debilitated stomach has rendered convalescence slow and difficult.

In Gastric and Intestinal Diseases Sanatogen has no Counter-Indication

"When there is gastric trouble with vomiting or sickness, Sanatogen is, in my experience, the best of artificial foods, easily retained and easily assimilated," writes an author in the "B.M.J."

In all gastric and intestinal diseases Sanatogen may be taken with confidence. Even in cases where the secretion of the stomach is greatly disturbed, the albumin in Sanatogen will be easily absorbed and retained by the organism.

Sanatogen is not only a concentrated food substance and regenerator, but also a physiological nerve tonic. Its combination of casein and glycerophosphate of sodium gives it an advantage over other food preparations, the nerve-cells themselves being nourished by the phosphorus it contains.

PYRIDIUM

Descriptive literature and samples of Pyridium gladly furnished on request.

MENLEY & JAMES LTD., 64, HATTON GARDEN, LONDON.

The chief characteristics and advantages of Pyridium include:

1 Powerful anti-bacterial action against several invading organisms, particularly those of the cocci type, also B. Coli com.

2 Freedom from toxic effects when taken in therapeutic dosage.

3 Ability to penetrate the tissues.

4 Marked power of stimulation to the proliferation of epithelial cells.

5 Early and gradual elimination through the genito-urinary tract.

6 Oral administration by means of coated tablets (each containing 0.1 gram of Pyridium).

Pyridium has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Pyridium is the registered trade mark of the Pyridium Corporation of New York to designate its preparation of phenyl-azo-alpha-alpha-diamino-pyridine hydrochloride.

It is Significant that so many of the Medical Profession when prescribing "Liquor Carbonis Detergens" add the word Wright's

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required for the complete extraction of all the soluble antiseptic constituents is attained by a series of complicated processes involving the use of highly specialized machinery.

On receipt of your professional card, a packet will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

ANTI-TYPHOID-PARATYPHOID (T.A.B.) ORAL VACCINE

Administration of this protective vaccine by mouth is now an established alternative to the usual hypodermic method for immunisation against the enteric diseases, and has the advantage of avoiding all reaction.

This method is especially indicated where rapid immunisation is desired, as in the case of contacts; or when facilities for hypodermic injection are lacking.

Issued in packages containing three doses of killed emulsion, with three bile tablets for oral administration on three successive mornings. Full instructions accompany the package. Price 17/6 per set.

Prepared under Licence from the Ministry of Health in the

LABORATORIES OF PATHOLOGY AND PUBLIC HEALTH,
6, HARLEY STREET, LONDON, W.1.

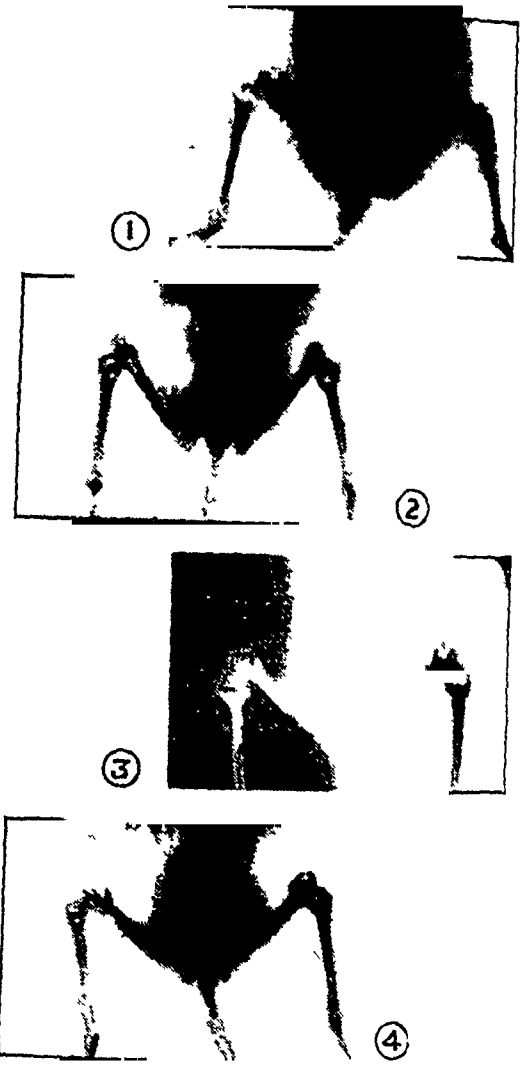
BETTER MILK FOR BABIES

FACTS ABOUT LACTOGEN

Vitamins and Minerals



To fulfil the requirements of the rapidly growing child an adequate supply of vitamins and mineral salts must be provided.

Milk furnishes a sufficiency of these essentials, and in Lactogen their complete conservation is effected.

For the final desiccation of the modified fresh milk the roller process is employed. The heat applied is thus reduced to a minimum and the exposure confined to a matter of seconds.

Lactogen provides a full complement of mineral salts in organic combination, together with the adequate vitamin allowance. It is a complete and balanced diet furnishing the infant with every essential necessary for good health and normal development.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

1 Rickets (faulty bone development) induced by a deficient diet Rat A
2 Recovery in the same rat after Lactogen feeding for 14 days Rat A
3 Rickets (faulty bone development) induced by a deficient diet Rat B
4 Recovery in the same rat after Lactogen feeding for 14 days Rat B
—showing that the antirachitic factor is present in Lactogen in full prophylactic amount

66 LACTOGEN 99
REGD TRADE MARK
BETTER MILK FOR BABIES

Lactogen is prepared in England by Nestles—famous for more than fifty years for the purity of their milk products—from the pure fresh milk of specially selected herds, grazing on picked English farms

Cow & Gate products for every infant idiosyncracy!

THE TRIUMPH OF COW & GATE

as the ideal food for babies when natural feeding fails is due to the fact that, apart from Cow & Gate Full Cream Milk Food for normal infants, a large variety of modified foods is also available providing for every possible constitutional peculiarity.

Here is a list of Cow & Gate Milk Foods :—

HALF CREAM. Indicated in cases where the fat metabolism is at fault. This condition demands a low fat content with a correspondingly high percentage of sugar. Very valuable for the first three months of life.

SEPARATED. Indicated in advanced cases of fat intolerance of the Cœliac type, also in post-operative feeding in pyloric stenosis.

BRESTOL. The Humanised Cream for Babies requiring additional fat. A valuable Vitamin Cream with a cod-liver oil base. Can be used in conjunction with any Cow & Gate Food to increase fat content.

HEMOLAC. Full Cream Cow & Gate Milk with Iron Ammonium Citrate for anæmic infants—as used in the recent investigations on Nutritional Anæmia (Medical Research Report No. 157, 1931).

FRAILAC. A milk food for frail and premature Babies, containing a low protein and high, easily absorbed, carbohydrate content.

LACIDAC. A Lactic Acid Milk prepared in three strengths—Full Cream, Half Cream and Separated, for all cases of gastro-intestinal disorders.

PEPTALAC. A pre-digested milk food incorporating wheat flour, recommended for both mothers and babies, and also, invalids with weak digestions, prepared in a moment by the mere addition of hot water.

LACQUIN. A tonic milk food containing tasteless quinine in a palatable milk base in sufficient strength for prophylaxis.

Cow & Gate Milk Food

"Cow's milk made safe and suitable for baby"

Clinical samples of any of the above products will gladly be sent on request, to members of the Medical Profession.

A Paper

ON

DIAGNOSIS AND TREATMENT OF COMMON INJURIES OF THE KNEE JOINT*

BY

NAUGHTON DUNN, M.A., M.B., CH.B.

LECTURER IN ORTHOPAEDIC SURGERY, BIRMINGHAM UNIVERSITY

Literature on injuries of the knee joint has been extensive, but to me accurate diagnosis in many cases becomes more difficult as my experience increases. There may be general agreement on the lines of treatment to be adopted for definite lesions, but not infrequently the accurate diagnosis is not possible. The reason for this seems to me to be that many of the ligaments, bursae, etc., described by the anatomists, are not directly palpable to the surgeon examining the joint. Before considering the question of diagnosis I think that it would make the subject clearer if I briefly refer to certain of the more important points which have been established with regard to the anatomy and physiology of the knee joint.

MECHANISM OF THE KNEE JOINT

The mechanism of the knee joint has evolved as a result of the function which it has been called upon to perform. It consists essentially of the broadened ends of the tibia and femur with a sesamoid bone—the patella—in the extensor tendon, and two intra-articular fibro-cartilaginous disks. It is the connecting link between the two longest bones in the body, so that body weight transmitted through these levers in movement of the joint subjects it to enormous strain. We therefore find that nature has provided it with powerful muscles for its control, and strong ligaments on which it largely depends for its stability.

Movements of the Knee Joint

Movements allowed at the knee joint are flexion, extension, and moderate rotation when the joint is flexed. These movements, except that of flexion, are limited by the ligaments. The fact that the articular surfaces of the condyles are not perfect arcs of a circle, and that that of the internal condyle is ¼in. longer than that of the external condyle, allows the femur to twist or screw inwards on the head of the tibia on full extension of the joint.

In this position the lateral and the anterior crucial ligaments are taut and tense, and the femur and tibia become practically one continuous rigid support, no antero-posterior or lateral movement being possible. If internal rotation of the femur on the tibia is maintained, flexion of the joint cannot occur. Before flexion commences the knee must unlock, and muscle action is then necessary for its stability. We thus see that where full extension of the joint is impossible constant strain is thrown on the quadriceps muscle. We all recognize that joints and the muscles controlling them usually have a common nerve supply, so that muscle atrophy is an early sequela of joint injury; but is it not probable that fatigue resulting from constant strain may account for the very marked wasting of the quadriceps which is so frequently seen when the mechanical locking of the knee in extension is not possible? In flexion of the knee moderate internal and external rotation are allowed, but little if any lateral or antero-posterior movement.

* Read in opening a discussion in the Section of Orthopaedics at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

ANATOMY OF KNEE JOINT

A knowledge of the relation of the intra-articular cartilages to the femur and tibia is essential to a proper understanding of common injuries of the knee joint. They are two crescent-shaped pieces of fibro-cartilage. They have at their extremities strong fibrous attachments to the rough areas in front of and behind the tibial spine. Both have weak attachments by means of the coronary ligaments to the peripheral margins of the tibial tuberosities. The internal meniscus is the less mobile because of its attachment to the internal lateral ligament, while the outer cartilage is separated from the external lateral ligament by the tendon of the popliteus muscle. The closer proximity of the cornual attachments of the external cartilage also anchors it less securely. The greater fixation of the internal cartilage probably accounts for the fact that it is more frequently damaged in cases of injury. It is also to be noted as a point of possible surgical importance that the anterior convex margins of the cartilages are frequently connected by a transverse ligament.

The behaviour of the intra-articular cartilages in movements of the knee joint is also of interest. It would appear that in flexion and extension they move with and on the tibia. *In extension their anterior part is compressed* by the femoral condyles—depressions normally present on the articular surfaces of these indicate this. In rotation the disks move with the femur on the tibia. Different parts of the meniscus come under special pressure during the various normal movements of the joint. One can therefore readily understand that undue strain may disturb the usual relations between the articular surfaces and the meniscus, so that a portion of the latter may become fixed and a tearing or displacement result. In any case rotation beyond normal limits is bound to strain or tear the attachments of the coronary ligaments to the head of the tibia. Rotation is only possible in flexion, and in my experience it is strain of the flexed knee which provides the very great majority of injuries to the intra-articular cartilages.

The Patella

The patella is a sesamoid bone developed in the extensor apparatus of the knee joint. It is connected by the patellar ligament to the head of the tibia. Deep to the patellar tendon, but extra-synovial, lies the large infra-patellar pad of fat.

Capsule and Ligaments

The capsule of the knee joint is itself a thin membrane, but is reinforced by strong ligaments and expansions from the muscles controlling the joint. The main ligaments are the lateral, crucial and posterior. Their points of attachment are well known. The functions of the ligaments are to prevent slipping of the bones on one another in extension, to keep them in proper apposition during movement, and to limit movement. All are taut in extension of the joint except perhaps the posterior crucial ligament, which is made tense by movements backwards of the tibia, but it is doubtful if it limits flexion.

Muscles and Bursae

For weight bearing in any position except full extension, muscle action is necessary for stability. These muscles are numerous and have strong attachments to bony points in close proximity to the joint. In relation to the joint and the structures controlling it at least 12 bursae have been described. Four of these—the supra-patellar bursa, those lying under the heads of the gastrocnemius muscle, and that surrounding the popliteus tendon—usually communicate with the synovial cavity.

Articular Cartilage

The articular surfaces of the bones entering into the formation of the knee joint are covered with hyaline cartilage. It is to be noted that it is avascular and so has little or no power of repair.

Synovial Membrane

The synovial membrane supplies the oiling system which ensures free movement in healthy joints. The point to be remembered with regard to it is that it is richly supplied with sensory nerves. Any damage to this structure is therefore accompanied by pain. It lines the capsule of the joint but is reflected over the infra-patellar pad of fat and crucial ligaments, so that these structures are intra-capsular but extra-synovial. It also covers the intra-articular fibro-cartilages on their articular surfaces. It does not cover the articular cartilage but is attached to the margins. The synovial membrane covering the infra-patellar pad of fat is prolonged to form an attachment to the intercondyloid notch. This is named the ligamentum mucosum, the lateral expansions of which form the ligamenta alaria.

DIAGNOSIS AND TREATMENT

In all joints, disturbance of the normal mechanism is due usually either to trauma or to infection, although even in cases of injury the possibility of neoplasm or neuropathic degeneration must be borne in mind. Trauma may be mild or severe—blows, twists or fractures. Infection may reach a joint directly through an open wound, or by haematogenous implantation. We must realize that the majority of strains of the knee, as of other joints, make a natural and full recovery without special treatment. The knee joint however is particularly liable to more severe strain because it has to sustain body weight transmitted through long levers, and whilst doing so allows a wide range of movement. It therefore provides many cases of injury, but I would suggest that we should confine our discussion to cases of chronic or recurrent disability following common injuries of this joint.

For the purposes of this communication I have reviewed 522 consecutive cases of which I have detailed notes of the condition found when the case was first presented to me.

Diagnosis in 522 Cases of Injury of the Knee Joint

Lesions of internal semilunar cartilage		179
Lesions of external semilunar cartilage		71
Lesions of internal lateral ligament		34
Loose bodies		34
Lesions of exterior apparatus		11
(a) Transverse fracture of patella	6	
(b) Rupture of quadriceps tendon	3	
(c) Rupture of patellar tendon	1	
(d) Avulsion of tibial tubercle	1	
Neuroma on patellar branch of internal saphenous nerve		7
Rupture of crucial ligament including fracture of the tibial spine		7
Lesions of external lateral ligament including rupture of biceps and traction fracture of head of fibula		7
Fractures involving articular surfaces of femur or tibia		4
Traumatic exostosis		4
Direct infection		4
Strain of posterior ligament		3
Osgood-Schlatter's disease		2
Haemarthros-Haemophilia		2
Traumatic dislocation of patella		2
Others		4
(a) Myeloma in external condyle of femur	1	
(b) Charcot's disease	2	
(c) Fibro-lipoma in vastus externus	1	
Indefinite lesions		147

These are cases of pain and limitation of movement following injury. Many of them were due to adhesions and responded to manipulative treatment. Others, where the history of injury did not entirely account for the condition found on clinical examination, I believe were cases of subacute infective arthritis. There still, however, remains a large proportion of cases in which a definite diagnosis is not possible, because of the facts that the attachments of certain muscles and ligaments are not accessible to direct palpation. In support of this belief I would point out that while anatomists describe 12 bursae in relation to the knee, surgical reference is available with regard to only 3 or 4 of these, all of which are, or become, superficial.

Surgical textbooks usually confine themselves to a description of commonly recognized lesions in relation to particular joints. The patient complains of pain, weakness, and/or limitation of movement in conditions such as tennis elbow, tenosynovitis, the presence of a ganglion, rupture of the *plantaris* tendon, etc. These cases are readily diagnosed when they occur in situations where the structures involved are accessible to direct palpation. This, however, is not possible in the case of many of the ligaments, bursae, etc., apt to be affected by strain of the knee joint.

There seems to me to be no reason why similar types of lesion should not occur in inaccessible portions of the knee, and I feel sure that this possibly accounts for much of the difficulty in accurate diagnosis. I propose to draw attention to points in diagnosis and treatment of the lesions of the knee joint in the order of frequency in which they occur in this series.

LESIONS OF THE INTRA-ARTICULAR CARTILAGES

To the lay mind the intra-articular cartilages alone are responsible for what is known as "football knee"; in fact, many patients will open their consultation with the statement that they have "slipped a cartilage," whereas close investigation reveals no such possibility. It is, however, on a correct diagnosis of the condition of these structures that successful treatment will frequently depend. The position of the joint and the exact strains to which it may be subjected at the time of injury are so problematical that they have ceased to interest me as a possible line of advance in treatment. My personal belief is that lesions of the intra-articular cartilages usually occur as a result of strain and protective muscular action when the joint is in a position of flexion. A lesion of an intra-articular cartilage may be readily diagnosed if there is a history of recurrent locking of the joint with pain and tenderness limited to the attachments of one of the cartilages, the joint being normal in function in the intervals between the acute attacks, and no *x*-ray evidence of any abnormality being present.

In this series of 522 cases, 250, or about half, were diagnosed as lesions of the intra-articular cartilages. In 179 the internal, and in 71 the external, cartilage appeared to be affected. Operation was advised in 160 of the internal cartilage cases and was performed in 139. The lesions found at operation were: detachment or fracture in the anterior half (19), detachment or fracture in the posterior half (64), bucket handle type (35), no definite lesion (21).

Of the 71 external cartilage cases 62 were advised to have operation, and this was performed in 46 cases. The conditions found at operation were: detachment or fracture in the anterior half (11), detachment or fracture in the posterior half (21), bucket handle type (4), cystic degeneration (3), no definite lesion (7).

Included in the series are 65 professional footballers. A consideration of these cases should be of special interest, since they afford examples of all the common injuries, and while giving rise to points for discussion as to diagnosis and treatment, the results establish the fact that a very high percentage of men return to the most strenuous

of games, after the removal of one or, in some cases, both cartilages. Further, my notes show that in the majority of the patients, manipulation by the bonesetter had failed to cure the condition.

Lesions Diagnosed in 65 Professional Footballers

Exostosis	2	,, ,, ,,	2
Secondary infection of infra-patellar pad ..	1	,, ,, ,,	0
Rupture of anterior crucial ligament	1	,, ,, ,,	0
Indefinite	3	,, ,, ,,	0

In one patient in whom the external cartilage was found fractured the *x*-ray showed very marked osteo-arthritic changes, but after operation he continued to play for a First League team, although some temporary synovial thickening and a feeling of aching in the joint recurred after a strenuous game. In only two cases of football accidents did a loose body in the joint appear to be the cause of the disability. In one the lower outer quadrant of the articular surface of the patella was found detached —the history was a typical one of recurrent lesion of the internal cartilage, but the *x*-ray revealed the loose fragment of bone, and operation was confined to its removal.

In the second case the *x*-ray revealed a loose body exfoliated from the articular margin of the inner condyle. At operation we found that this body was obviously a portion of the normal articular cartilage, not completely detached but hinged at its anterior margin by a fibrous attachment. The history of this case differed from the preceding one in that the man had occasionally had some aching in the joint previous to the first attack of locking. That he was not able to satisfy me that the knee had always been absolutely as good as the other before the original accident is, I think, a most important point in helping to elucidate the differential diagnosis in lesions of the knee joint.

Of the 9 cases of injury of the lateral ligaments none has been associated with lesions of the cartilages except one in which, in addition to damage to the internal lateral ligament, a rupture of the anterior crucial ligament had occurred. In this case operation was confined to the removal of the internal meniscus because in my hands the results of operation for replacement of a deficient anterior crucial ligament certainly do not suggest the possibility of the patient again playing first-class football. Removal of a cartilage which is obviously causing recurrent increase of disability in cases of crucial ligament injury is, however, advised.

I have not operated for repair of the crucial ligaments except in war injuries, the operation performed being that advised by Hey Groves and Alwyn Smith. My experience of the operation has been that stability of the joint was definitely increased, and for 6 months appeared to be almost a perfect success, but later examination always showed the presence of a degree of antero-posterior movement which did not justify the removal of splintage. If you read the history of the published cases you will usually find that a fractured cartilage was removed at the time of operation, and I have always had the feeling that the removal of a troublesome meniscus was not an unimportant factor in the patient's satisfaction with the result obtained. Even normal cartilages can be a source of trouble in knee joints in which rupture of the crucial ligaments is complete. A displaced or fractured cartilage is subject to more frequent displacement, so that its removal gives patients a sense of stability which previously they had not known. The history of another of the cases is very interesting and instructive.

Having had an operation for removal of the internal cartilage, and being still unfit for play, the player was given a free transfer from one club and accepted by another. He was still unfit and was then referred to a well-known bonesetter in London. When I first saw him he still had definite signs of a recurrent displacement of something on the inner side of the joint, and as the *x*-ray was negative I advised further exploration. At operation it was obvious that only the anterior portion of the cartilage had been removed at the previous operation, while the true lesion was a detachment of the posterior half which was readily drawn into the centre of the joint. This man left the nursing home on the 12th day, played his first game for the club six weeks after operation, and has since scored many goals for his side.

This case opens some interesting points for discussion. It raises the question of what should be done if with a very definite history of recurrent trouble, pointing to lesion of a particular cartilage, one explores the joint. One may find a lesion of the anterior part, or a bucket handle displacement of a portion of the cartilage into the centre of the joint. In the former case I think it is sufficient to remove as much of the anterior two-thirds of the cartilage as is possible without strong traction, and in the latter to remove the obviously detached portion. If no definite lesion is seen, the condition of the posterior portion of the cartilage can only be known by its removal, and this, I am sure, is necessary. It will then usually be found that on further peripheral dissection and traction the main body of the meniscus becomes displaced into the centre of the joint. This would not occur with a normal cartilage, so we are satisfied with the operation, and expect and usually get a joint which gives no further trouble.

It is, however, to be noted that the portion displaced into the joint is not always the entire cartilage. In fact, I believe that it is commoner to have a longitudinal tear of the cartilage than a separation from its true attachments. This means that after the operation described, a portion of the periphery of the posterior segment of the cartilage is still present, and its attachments may have been loosened as a result of the original injury. Its removal would necessitate another incision, and, personally, I am inclined to be satisfied if I feel I have dealt with the main lesion. We must, however, remember that further trouble may occur as a result of the displacement of the remaining portion of the cartilage. I have myself experienced it in three cases of which the following history is typical.

Case A.—Definite history of recurrent displacement of internal cartilage. Knee had locked on previous occasions, but he had always been able to reduce it himself, and would play several games without trouble. On this occasion, while playing, the knee locked and his usual manipulations failed to allow extension. At operation the posterior two-thirds of the cartilage appeared to be detached and displaced in front of the point of contact between the inner condyle of the femur and the head of the tibia, while the attachment of the anterior portion of the cartilage was normal. As a matter of interest manipulative reduction with the structure exposed was tried and failed, but we deal with this point later in relation to manipulative surgery. Freeing of the anterior attachment allowed displacement of the obviously detached portion into the intercondylar space, and it was removed. The young man returned to full activity and played several matches without any recurrence of his old trouble. The following summer, i.e., 9 months later, he came to me complaining that he had had a recurrence of trouble on the inner side of the same knee, the history being that he had one leg in a punt and one on the bank, when the punt drifted out and the knee on the bank

in the flexed position was subjected to strain, gave way, and he felt something move in the joint. Examination revealed tenderness over the joint line on the inner side, and as he had had several definite sensations of something slipping in this region since this accident, I decided to re-explore the joint. The peripheral portion of the posterior half of the internal cartilage was found to be detached. Since its removal, 4 years ago, the man has played football regularly and has had no recurrence of trouble.

The next question that arises in surgery of the knee joint is: "What are we to do if we have an absolutely typical history of recurrent displacement of the internal cartilage, and, the *x*-ray being negative, we explore the inner side of the joint and remove what appears to be an absolutely normal cartilage?" My personal feeling is that if we are absolutely satisfied with our diagnosis of a recurrent displacement of a meniscus the outer side of the joint should be exposed, unless there is any particular reason why we should not do so. I remember particularly one case in which the history I got was so convincing that at the operation, at which I was assisting my colleague, Mr. F. G. Allan, after a perfectly normal internal cartilage was removed with the usual difficulty, I suggested that with a history such as we had, some definite lesion should be found, and on retracting the patellar tendon and infra-patellar pad of fat we were able to see that the external cartilage was abnormal. A small incision on the outer side of the joint allowed removal of the anterior two-thirds of the external cartilage which was attached in front, but a longitudinal split and fracture rendered a portion of the anterior two-thirds free in the joint cavity. Since removal of his normal internal cartilage and the detached portion of the external cartilage the man has had no further trouble. This case illustrates the surgeon's difficulty. Are we to be satisfied with finding no definite lesion of a particular cartilage when the history clearly indicates a recurrent locking of the joint as the result of injury, and the symptoms and physical signs point definitely to an injury of that cartilage? I will make the question more difficult by referring to another case.

Mr. H. asked me to see one of his house surgeons with regard to his knee joint. The patient was an exceptionally strongly built doctor 28 years of age, and still actively interested in rugby football. As a result of examination, and from the history he gave, I felt quite sure that a portion of the internal meniscus had been detached or fractured, and that operation was necessary to restore his full activity. At operation no lesion of the internal cartilage was found, and I removed the greater part of the cartilage with difficulty. As he was a doctor, I decided to confine myself to what I had told him I should do, and asked Mr. H. to tell him that we had found nothing wrong with the internal cartilage, and if the trouble recurred we might consider exploration of the outer side of the joint. Mr. H. did not tell him anything of the apparent failure of our surgical effort, and the young man whose knee used to give way and lock when he was running to catch a bus, has to my knowledge played 15 games of rugby football without trouble in the knee from which we removed what appeared to me to be a normal meniscus.

Another case which complicates the question is the possibility of both cartilages having been torn as a result of one injury. We know that in taking our history of a recurrent case the patient is often indefinite about the side of the joint to which the pain was referred at the time of the injury, and with recurrent displacements it may also vary. In these cases I always make the diagnosis on the site of tenderness after a recent injury, but if some time later a patient presents himself with a definite story of recurrent displacement of a cartilage with pain referred sometimes to the inner and sometimes to the outer side of the joint, I will not operate, but request that the knee be tested and the patient referred to me for further examination as soon as possible after the next injury.

If after a recent injury, which the patient states is similar to previous ones, I find tenderness on the line of the inner or outer side of the joint, I advise operation accordingly. That this is not always a safe procedure is illustrated by the following case sent to me by the medical adviser of a certain well-known association football club, who suggested that the young man was suffering from an injury to his external cartilage. My examination, however, pointed definitely to a lesion on the inner side of the joint, and at operation I was particularly pleased to find a bucket handle displacement of the internal cartilage, and after its removal closed the joint. It was reported to me that the knee had given way and again locked when the patient was getting out of bed prior to discharge 14 days later. Pain and tenderness now were referred to the outer side of the joint, and exploration revealed a similar lesion of this cartilage. Since this occurrence the knee has resumed and retained normal function.

The only other type of case in which no *x*-ray changes are shown which might simulate cartilage displacement is that of lateral displacement of the patella. Many times patients will describe the displacement of an internal cartilage as a displacement of the patella, but although the latter is rare it does occur. If in doubt, I would suggest that the best way of making sure whether displacement of the patella is the cause of recurrent disability is to have the knee tested in a gymnasium, and examined by someone sufficiently experienced immediately the trouble complained of occurs. If this is not practicable, then while the patient is anaesthetized, and just before the tourniquet is applied, test the mobility of the patella. If it is readily displaced laterally while that of the other knee does not allow of lateral displacement, the patient's diagnosis is possibly right.

Lesions of the Lateral Ligaments

It is of interest to note that in this series, where strain or rupture of a lateral ligament was diagnosed, there appears to have been no case where a lesion of an intra-articular cartilage was also present. Furthermore, a complete rupture of the internal lateral ligament did not occur in any of the 34 cases in which a lesion of it was diagnosed, and recovery took place with conservative treatment. Of the 7 cases of injury to the external lateral ligament, complete rupture with laxity of the joint was present in 4, including 2 cases in which the biceps tendon was separated from its insertion. In these 4 cases operation was necessary to secure stability of the joint, and the results were excellent. One case in which there was a traction fracture of the head of the fibula made a perfect recovery without operation. This rather suggests that a complete rupture of a ligament is likely to be a more serious disability than a traction fracture of its attachment. The histories of two of this year's association football cup finalists are interesting.

Both patients indicated strain of internal lateral ligament of the knee joint, with possible displacement of the internal semilunar cartilage. Both were tender over the line of the joint on the inner side, but more tender over the femoral attachment of the internal lateral ligament. They were treated as strains of this ligament. The line of treatment advised and carried out was elevation of the heel of the boot, raising it on the inner side to prevent strain on the injured ligament, with electrical treatment of the quadriceps muscle, and a pad and strapping over the tender area on the internal condyle. One of the cases came under my care on September 3rd, 1927. He was discharged from treatment on October 7th, when local tenderness had subsided, and all forced movements were free and painless, and has since played regularly in a first division team. The other case was first referred to me on

March 31st, 1931, three weeks after the date of his original injury. I advised treatment on the aforementioned lines, and though there was still some tenderness of the femoral attachment of the internal lateral ligament, he played in the cup final four weeks later, with the knee tightly bandaged, and afterwards was playing for his club on a tour abroad.

These two cases alone satisfy me that although local tenderness on the line of the internal cartilage may be present, if tenderness of the attachments of the internal lateral ligament is also present it is wise to treat the lesion of the ligament, and wait for further evidence of true cartilage injury before advising operation.

Loose Bodies

Apart from diagnosis of the nature of gross lesions of the main articular surfaces, *x*-rays are particularly valuable in establishing the possibility of loose bodies or fracture of the tibial spine, as causes of recurrent or chronic disability following injury. Loose bodies are not infrequently present in the knee joint without giving rise to symptoms sufficiently severe to demand medical attention. There may be some "rheumatism" of the joint, and occasionally a feeling of something catching in a knee, or a sudden severe pain may cause the patient to seek medical advice. Until an *x*-ray is taken in these cases the true state of affairs is not likely to be recognized. The joint may then be found to contain many loose bodies, large and small; an *x*-ray of the other knee, of which no complaint is made, may show a similar picture. I do not propose to deal with the pathology and treatment of this type of case, but draw attention to them because they may either cause a very temporary locking of the joint, or a permanent locking may occur—i.e., persistent limitation of extension as a result of a moderately large body becoming wedged in the intercondyloid notch in front of the attachments of the crucial ligaments. In this case removal of the body is necessary to allow extension of the joint.

Fractures of Tibial Spine

With regard to fractures of the tibial spine, I am not satisfied that the *x*-ray appearance always justifies operation. It is usually possible to obtain full extension of the joint by manipulation or by gradual splintage, and although I realize that this position may not be the most favourable for the repair of a ruptured crucial ligament, it certainly allows repair of a fracture of the tibial spine, and a restoration of normal function.

Exostosis

X-rays may also reveal detached bone fragments or exostosis some weeks after injury to the lateral ligaments. If the stability of the joint is good as a result of conservative treatment, these should be dealt with surgically only if they give rise to trouble. In connexion with this question of ligaments and exostoses I must mention a case of particular interest.

Mrs. D. had for three years been unable to take part in sports because of a recurrent severe pain referred to the inner side of the knee if it was subjected to strain. Examination revealed a definitely tender point over the inner condyle of the femur, and pain was referred to this point on forced abduction and external rotation. The *x*-ray was negative. I decided eventually to force movements, but also to explore the tender area. I found there a tiny, sharp spicule of bone with a bursa around it, and have always felt that the removal of this rather than the manipulation was the cause of complete cure.

Lesions of Extensor Apparatus

I report 11 cases resulting from indirect injury to the extensor apparatus of the knee joint. Time does not allow of a full review of the possible causes and the detailed treatment of these lesions. The diagnosis is usually easy. The patient is unable to extend the limb voluntarily and fully, while passive extension is possible, and the point of tenderness will indicate the site of the lesion. This would appear to me to depend on the relation of the patella to the condyles of the femur when the protective contraction of the quadriceps muscle comes into play. As a rule the more limited the degree of flexion the lower the lesion. The following lesions may occur: separation of the tibial tubercle; detachment of the ligament from the lower border of the patella; transverse fracture of the patella; separation of the quadriceps tendon from the upper border of the patella. As a result of the strong action of the quadriceps, considerable separation may occur at the site of rupture, so that surgical treatment is usually necessary.

These observations as to the site of lesion are based partly on experience of mobilization of knee joints in war surgery, but also on the fact that the three cases of rupture of the quadriceps attachment to the patella occurred in gentlemen late in the evening, at a time when their cerebral control of muscle action might have been somewhat delayed. I surmise that perhaps earlier in the evening the protective action of the quadriceps might have been more prompt, and no lesion, or perhaps fracture of the patella, occurred.

Indefinite Lesions

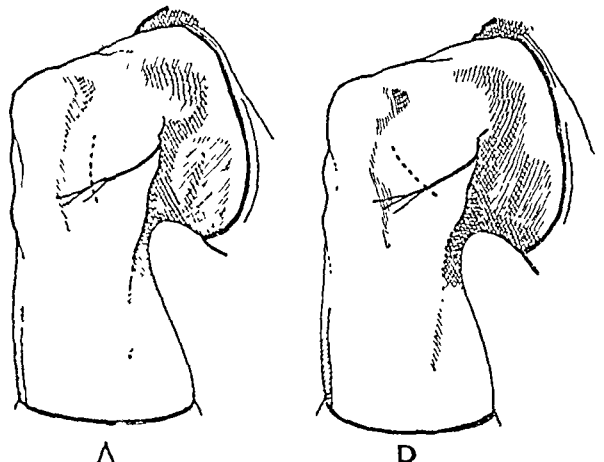
These number 147 of the 522 cases reviewed. I feel that they should include several cases in which everything in the history appeared to suggest a definite lesion of a cartilage. The cases I have in my mind include the following histories.

(1) A girl aged 26, seen 10 weeks after her accident. Her doctor states that the knee was dislocated as the result of a twist while playing golf, and that he reduced the displacement under an anaesthetic. Since this, extension of the joint has been limited by 30 degrees.

(2) Mrs. W., aged 43, while being helped off a cliff three weeks previous to examination, had a feeling of something tearing inside the joint when it was acutely flexed. On examination I found tenderness on the line of the joint on the inner side, and pain on forcing extension.

In one of these cases manipulation failed to produce comfortable extension of the joint, and in neither was this possible after exploration and removal of apparently normal internal cartilages. Although I mention only two of the cases, I have come to realize that diagnosis of a true primary cartilage displacement is a very much more difficult problem than are cases in which there is a history of recurrent trouble. If the movement of flexion, as well as extension, is limited, and there is general tenderness of the joint margins, it is unlikely to be a simple cartilage lesion. A traumatic or subacute infective arthritis occurs in the knee as in other joints after a severe injury, so that limitation of extension does not necessarily mean that this is due to cartilage displacement, even although this probability is strongly suggested by the history.

Manipulative Surgery

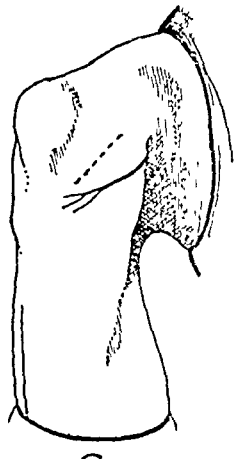


In other cases of indefinite lesions I include those in which the question arises whether the condition is likely to be relieved by manipulative surgery. This seems to me to be a branch of surgery which might with profit to the public be employed more frequently by the profession, and certainly less frequently by those whose record, as we know it, does not indicate that they have the fundamental knowledge necessary for its judicious use. It consists essentially of ensuring the normal range of movement of a joint in every position. In the knee joint attention must also be paid to securing normal lateral mobility of the patella and as far as possible of the intra-articular cartilages. There can be no mystery about this. The only question that arises is at what stage should

we apply it. It should always be utilized to ensure full extension of a joint where displacement of a cartilage is probable, except in cases of recurrent displacement, when the diagnosis is clear. In these cases the patient should be offered, or rather advised, to have the alternative—that is, operation—which will almost certainly prevent a recurrence of the trouble. The majority of cases which bonesetters cure are, however, cases of joint strain which have recovered from the usual reactions of a joint to trauma or mild arthritis, but the patient still complains of pain on certain movements. During the stage of active reaction forcing of movements can do nothing but harm, but there does come a time following joint injury at which forcing of movements, although painful at the moment, may be dramatically effective in its results.

I feel quite safe in saying that at least 90 per cent. of the professional footballers on whom I have operated have previously had their joints manipulated by a bonesetter. We may agree that manipulative surgery is not adequately taught in our medical schools, but in spite of this it must be clear to all who deal with joint injuries that the popularity of the bonesetter is more largely due to the fact that, as in the case of many popular remedies, successes rather than failures are widely advertised in the lay press.

Operative Approach for Internal Derangement of the Knee Joint



The surgical approach to the knee joint should ensure as little damage as possible to the joint structures. Incisions which divide the patella or disturb the normal attachments of muscles or ligaments should be avoided unless absolutely necessary. Personally, I use the split patellar route only for the repair of the crucial ligaments. It has the one great advantage in that while it allows free access to the joint it does not necessitate detachment of the tibial tubercle, so that after operation the joint can be treated in the position of flexion desired, without risk of subsequent separation of this structure. For removal of loose bodies which cannot be fixed and evacuated by direct incision, I prefer one or more small incisions supplemented by digital examination. Single incisions are usually sufficient for removal of the damaged portion of

A and B.—Incisions commonly used for exploration of the inner side of the knee joint

either the internal or external intra-articular cartilage. Occasionally a small supplementary posterior incision, as described by Alwyn Smith, is necessary to deal adequately with a lesion of the posterior segment of the cartilage.

It will be noted that in this series operation has been necessary in 7 cases for the removal of neuromata of the patellar branch of the internal saphenous nerve, which had been divided as a result of the incision used for exploration of the inner side of the joint at a previous operation. In 1916 my attention was first drawn to the importance of the line of the incision for the removal of the internal meniscus. In that year an officer presented himself at the orthopaedic hospital at Shepherd's Bush and stated that since the removal of his cartilage he had had no recurrence of definite locking, but that he had a tender nodule in front of the joint, and that the slipping of this over the margin of the inner condyle on flexion of the knee gave him pain and a sense of weakness. I excised the scar and he returned to France. Three months later he reappeared, and said he had lost the old sensation of pain on flexing the knee, but that he had developed a tender nodule over the inner condyle which gave him pain when riding. I removed this nodule, which was obviously a nerve bulb, by avulsion. As far as I know he had no further trouble. It was obvious to me that this was a nerve bulb on the patella branch of the internal saphenous nerve, and that the possibility of the complication which might result from its division had not been fully recognized. Since 1916 I have adopted an incision which avoids the possibility of division of this nerve.

C.—Incision advised to obviate complications following division of the patellar branch of the internal saphenous nerve.

This has the advantages that we cannot get the sequela of a painful neuroma in the scar, or the anaesthesia commonly complained of in the area of distribution of the patellar branch of the internal saphenous nerve. Both are points of great importance with regard to the treatment of professional footballers especially, as unless the limb feels absolutely normal confidence in it is unduly delayed. The essential point of the incision which I employ is that it runs parallel with the patellar branch of the internal saphenous nerve, and allows of its retraction before the capsule is incised.

Summary

(1) It is not possible to discuss adequately common injuries of the knee joint in a paper limited to 5,000 words.

(2) While the anatomy and physiology of the joint are well known, only lesions easily demonstrable clinically, or by *x*-ray examination, are described in surgical textbooks.

(3) This investigation of 522 consecutive cases of injury to the knee joint demonstrates that almost 50 per cent. are lesions of the intra-articular cartilages.

(4) While accurate diagnosis of an original injury may be difficult, the cause of recurrent lesions can usually be established as a result of a carefully taken history, together with the clinical and *x*-ray findings.

(5) Indefinite lesions are common. I believe that they include conditions analagous to tennis elbow, tenosynovitis, etc., commonly referred to in relation to other joints. The inaccessibility to direct palpation of certain regions of the knee joint probably accounts for this.

(6) While conservative treatment or manipulative surgery is successful in many cases, a surgical exploration of the joint will always be necessary for the cure of a large number.

(7) In the surgical approach to the inner side of the joint, incisions which may divide the patellar branch of the internal saphenous nerve should be avoided.

I am grateful to my colleagues, Mr. A. M. Hendry and Mr. Maister, for their help in reviewing this series of cases, and to Dr. Brailsford for preparing the slides and photographs.

DIAGNOSIS AND TREATMENT OF ACUTE OTITIS MEDIA*

BY

H. V. FORSTER, *M.C.*, M.B., Ch.B., M.Sc.

LARYNGOLOGIST, LIVERPOOL ROYAL INFIRMARY; LECTURER IN LARYNGOLOGY, UNIVERSITY OF LIVERPOOL

Acute otitis media is a disease quite regularly described as either catarrhal or purulent in type, the first being a mild form of the second or perhaps its earlier stage. An allergic type should be kept in mind.[1] There is, however, a catarrhal variety which should be recognized as a definite clinical entity because fluid collects in the tympanum and is not easily dispelled—a *hydrops e vacuo*, perhaps, or at most the exudate of a mild inflammatory process. Pain is made little of, but fullness in the ear, deafness and head noises constitute the train of symptoms. This picture contrasts sharply with the typical attack of acute purulent otitis media with which the following observations are chiefly concerned.

Acute Purulent Otitis Media

This as a rule is a definite bacterial infection. Pain, often excruciating, warns the unhappy subject, Nature crying out in alarm because a sense organ is in jeopardy. An invasion of the middle-ear cleft may mark the ruin of the auditory and vestibular systems and give rise to very serious intracranial and general complications. Such a gloomy picture with complications is fortunately the exception, but it obtrudes regularly enough to act as a stimulus and to encourage early operation in acute middle-ear disease.

Bacteriology

Of several microbic invaders a streptococcus is the common one. Smeall[2] quotes statistics of 120 swabs from the middle ear and mastoid from the ear, nose, and throat department of the Edinburgh Royal Infirmary as follows:

Haemolytic streptococcus	73	90, or 75%
Other forms of streptococcus	17	
Pneumococcus	17, or 14.2%	
Staphylococcus	11, or 9.2%	
Diphtheroids	2, or 1.6%	

Hadjopoulos[3] classifies the usual streptococcic flora of the nasopharynx in terms of oxygen requirements. Under pathological conditions there is a reversal of the percentage in favour of the more pathogenic facultative aerobic types (*Pyogenes mutis* group), which is exactly the state of affairs when swabs taken at operation from cases of acute mastoiditis are examined. The pneumococcus fortunately was rarely found, and was then of Type 3 as a rule. This variety (often called the *Streptococcus mucosus encapsulatus*) invades, however, by stealth, an insidious onset leading to disaster at a later stage. After Type 1 infections, survival is more probable. The otologist will no doubt recall cases of pneumococcal meningitis in the presence of intact tympanic membranes but with a history of previous ear discharge, and there are also other examples of pneumococcic invasion of the meninges taking place almost at the same time as the onset of discharge from the middle ear.

Etiology

Among the causes of acute middle-ear inflammation the common cold takes an important place, as well as influenza and sinus disease awakened by the attack—in fact, any acute infection of the upper respiratory tract, sometimes even pneumonia, where invasion may take place along the Eustachian tube or perhaps by way of the blood stream. Each summer an outbreak occurs in the bathing season. Infection passes via the Eustachian tube unless an old damaged ear allows access by way of the external meatus. The micro-organisms of public swimming baths and of the sea are blamed; but no doubt the upper respiratory passages of the victim supply the lurking streptococcus, and in such a manner, too, the enthusiastic user of the therapeutic nasal douche occasionally suffers. In the early stages of a cold in the head, it is as indiscreet to go swimming as it is to use the nasal douche.

Of the acute specific infectious diseases, scarlet fever and measles predominate as invaders of the middle-ear cleft. They stand supreme as sources of lasting and permanent damage. The former, a recognized streptococcal malady from the start, shows, when attacking the tympanum, signs of rapid destruction, though in the symptoms an element of contrast is lost because the patient is already debilitated and miserable from the original disease. Information received through some complaint of pain would, however, be supplemented by the fresh rise of temperature, though such information may be lacking altogether. Discharge from the ear may anticipate arrangements to open the drumhead, and particularly if the consent of the patient has not been previously obtained at the time of admission to a fever hospital.[4] Fever hospitals have already taken charge of these cases for a considerable number of years, and the appointment (rather long delayed) of otologists to these institutions should provide a wider knowledge of the signs in the earlier stages of scarlatinal otitis media.

In measles the complication may take place at a later stage; pain, perhaps brief in duration, should leave the rising temperature curve as a useful guide, and so should a relapse in the general condition of the sufferer. A factor of indolence or latency in the middle-ear condition must not be forgotten, and the observer should anticipate this in his examination of the drumhead. Even a history of ear discharge of brief duration should not be allowed to deceive him. The sealed drumhead may need to be opened again. Kerr Love[5] gives measles the first place, even above scarlet fever, as the origin of much chronic ear discharge in school children. Early recognition and treatment, therefore, in the acute stage might help to avoid this.

Other indolent or quasi-latent acute middle-ear attacks may take place throughout life. A typical mastoiditis acuta with an intact drumhead is sometimes a final stage, but it is in the infant that French observers have endeavoured to establish the presence of a particularly quiet type of the disease—latent otitis—and many otologists will remember the questionary circulated by Le Mee, Bloch, and Cazejust in 1924, and the monograph on this subject written by the two former.[6]

In infants very sharp attacks with screaming and meningism sometimes occur, but in the following description the symptoms are moderate and less clear. Acute middle-ear disease in the infant may be an embarrassing problem. The baby with a cold of perhaps a week or ten days' duration is noticed to be restless at night and to cry out, yet during the next day it would appear to be moderately well, but as bedtime returns the troubles of the previous night are repeated, and the temperature rises, though I have seen this rise delayed. As the disease progresses, changes in the colour of the face are noted—a pallor of the cheek on the side of the lesion and then a general sickly aspect. Interference is perhaps postponed and discharge eventually appears.

Examination of an infant's ear is no simple matter, and it would be as well to approach at feeding time when the attention is concentrated on the breast or bottle.

* Read in opening a discussion in the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Eastbourne, 1931

Once crying or struggling takes place injection of the vessels of the drumhead and even a little bulging occur. Pressure in front of the tragus, which is said to cause pain, should be avoided, too. While the infant's tympanic membrane more or less equals in size that of the adult, the entrance to the meatus is small; having negotiated this, the drumhead, instead of being found to face the observer at a comparatively easy angle, as in the adult, is here somewhat on edge, and not easy to see. Surprisingly resistant to rupture at this age, it may first be seen when the disease has progressed sufficiently to disguise its pearly surface so that it appears to merge imperceptibly into the posterior meatal wall. Should trouble involve the other ear one may profit from the lesson taught by the first. The result of an early and successful paracentesis may be quite dramatic; the child falls asleep and progress is uneventful.

From infancy to childhood brings us to the time when enlargement of the respiratory tonsil leads to the condition called adenoids, and now and during the earlier days of school life this trouble in the nasopharynx receives much blame for damage in the middle ear. Fortunately as the years pass by, the length of the Eustachian tube increases and the tympanic cavity lies further away from the nasopharynx, the nasopharynx itself becoming more spacious. Such changes are favourable to the auditory organ, until we find the adult not so much a victim of recurring middle-ear mischief as a sufferer from less frequent but more definitely established attacks.

These remarks lead to the wide problem of predisposition, but space will allow only a few brief observations.

1. The hereditary factor, for example in acute middle-ear suppuration, has impressed me more than it has done in so-called chronic progressive middle-ear deafness.

2. Congenital defects should also be mentioned. In cleft velum palati it is difficult to recall from memory a case not showing perforated or damaged drumheads in later life or with a liability to further middle-ear trouble.

3. Atrophic disease brings further interest to the problem. In atrophic rhinopharyngitis one looks to find damaged drumheads or a liability to recurrent otitis media.

4. Finally, the maligned lymphadenoid tissue of the uppermost parts of the respiratory tract should not be looked upon as the origin of all middle-ear inflammation in children, for there are many who, in spite of a perfectly executed tonsil and adenoid operation, contract it later, developing perhaps acute mastoiditis, too, and suffering an occasional fatality from meningitis.

Clinical Signs

What is the changing picture of the drumhead in this acute disease? The blood vessels of the drumhead, usually collapsed and lacking in colour, stand out vividly. An aural microscope would probably show the main supply, which runs to the handle of the malleus, to come by way of the posterior fold, avoiding the membrana flaccida; less numerous vessels pass immediately below this group.[7] Next, the inflamed tympanic mucosa shows through, casting a blush upon the face of the drumhead. The insertion of the membrane into the tympanic ring loses definition. The deep meatal wall, now growing angry, refuses to be distinguished easily from the drumskin itself, the pearly colour of which remains for a while in front of the umbo; even this disappears. The handle of the malleus is difficult to see; only its short process stands out as a landmark. The posterior superior quadrant may now begin to sag. It is, of course, this area which one sees blown out by inflation in the quiescent drumhead. Most probably the presence of abundant small vessels in the anterior part gives to it the very deep colour during inflammation; but just because it appears to bulge the best therapeutic result will not by any means necessarily follow its incision in acute otitis media; and by entering the knife too high and rather nearer the short process of the hammer bone it is possible to sever and cause damage to the main blood supply of the drumhead (Potter). It is surely better for several reasons to incise the lower part.

Incision of Drumhead

When should the drumhead be divided? Pain, of course, is the symptom which calls most frequently for an early incision of the membrana tympani. If the patient has lost one night's sleep and seems likely to lose another, the operation should not be delayed, but if the bursting of superficial blebs on the membrane is accompanied by relief of pain, interference may not be needed. With pain less severe, the presence of pyrexia, the general condition of the patient, the appearances of the membrane, and the degree of deafness must help the decision. Blebs or bullae are by no means all of one kind; some arise from beneath the superficial epithelium of the deep meatus or at the margin of the annulus, and are of considerable size, advancing outwards. When opened they are seen to be filled with blood clot, and if arising in acute otitis media, unless the hidden drumhead is also pierced, relief will not be obtained.

An objection to early paracentesis tympani is the difficulty of the operation. The description of the proceeding sounds easy enough, but in actual practice to carry it out accurately is not so easy. Myers describes well the danger zones within the tympanum.[8] An incision upwards into the superior quadrant may divide the chorda tympani nerve, and, in passing, strike the junction of incus and stapes; an incision downwards or across the lower quadrant appears safer. It is unlikely that the adjacent round window will be damaged by this method of approach, and an exposed jugular bulb will rarely be found. It is, of course, remotely possible to injure the carotid artery in the tubal area.

Ethyl chloride anaesthesia, rather than nitrous oxide narcosis, allows of a more deliberate operation, and when only chloroform or ether is available under difficult and undesirable conditions the operator at least need not complain. With the patient lying on his back on an operating table, and his head turned well to one or the other side to avoid the shoulder, conditions are certainly at their best. An acutely inflamed drumhead with the deep meatus inflamed in sympathy is not a too well-defined target, and the older method of pricking, which has given way to incising or cutting, is certainly much better treatment than no interference at all. The American instrument of Dintenfass, which I intend to try in this way, is V-shaped in section, a miniature trowel with a sharp-pointed "business end."

The immediate results of incision of the drumhead in acute otitis media are most varied. The resistant drumhead gives way under the knife with a loud crack, and the hissing noise of abundant fluid or sero-pus under pressure, or there is a frank escape of creamy pus before blood obscures the view. Less striking is the escape of some muco-pus through the indolent drumhead, for example, in a case of measles. Or, again, the immediate result may be rather disappointing when dividing the fleshlike membrane guarding a tympanic cavity, the inflammatory contents of which feel semi-solid and resistant; a discharge of pus, however, takes place later. Allergic cases (Proetz) are said to be likewise resistant and give forth little discharge, urging the operator later to repeated incisions when inactivity would have been preferable. The allergic condition may be converted into a purulent one by such interference

After-treatment

Whether in the after treatment of the case the medical attendant favours the so called dry method of mopping out, or the method of frequent washing out by syringing, irrigations must be employed if the discharge becomes tenacious, and even when discharge is free occasional relapse and disappointment can be overcome by a thorough but gently performed wash out with a mild isotonic saline or alkaline lotion Kernison[11] strongly advocates washing out almost immediately after paracentesis, to avoid gumming up of the incision by blood clot or fibrin In the later stage, too, irrigations with a mild mercurial lotion and the use of the suction speculum may result in resolution and avoid further operation as the time approaches to suggest drainage through the mastoid, namely, in three to six weeks

Differential Diagnosis from Other Causes of Acute Earache

Acute pain felt in the ear may be caused by troubles at a distance, or by local troubles, not middle ear inflammation

Referred pain from a tuberculous laryngitis, malignant growths of the posterior parts and side of the tongue, malignant disease of the pyriform fossa—these are well known More simple causes may be a carious molar tooth, and a partly erupted or impacted wisdom tooth must not be forgotten Sharp pain in the ear is noted in acute tonsillitis, particularly when peritonsillar inflammation is added, but, of course, an actual middle ear inflammation may follow as well A tonsillolith may prove a hidden cause Accessory sinus disease has also been blamed for pain referred to the ear, and in conclusion one does see a few cases, chiefly in young women, where no cause whatever can be discovered on examination

There is, of course, the occasional case of mumps when middle ear trouble or mastoiditis has been wrongly suspected A dental abscess has been seen to discharge from the external meatus But undoubtedly the commonest cause of pain, sometimes difficult to dissociate from a middle ear attack, is infection in the skin of the meatus I refer to furunculosis and to the dermatitis which we conveniently call eczematous, and occasionally the diagnosis presents very considerable difficulty Undoubtedly the pain in such cases is often referred to the front of the ear, or below it, and when infection reaches the mastoid lymphatic gland a true mastoiditis may be wrongly suspected The unpleasant condition of pediculi capitis has been responsible for an error of this kind

Sometimes when cerumen becomes impacted in the deep meatus, but particularly in that stubborn form of impaction called keratosis obturans, very great pain may arise deep in the ear (not to forget collections medial to exostoses of the canal), and it may be exceedingly difficult to decide whether the inflammation of the drumhead has been set up by such mechanical conditions, or whether an acute otitis media lies beneath The difficulty sometimes experienced in clearing the meatus for diagnosis, and the very great pain involved in any such manœuvre, provide a situation extremely trying for both patient and doctor

Foreign bodies, whether introduced from without or human material becoming foreign, as described above, may cause inflammation of the drumhead, or, to give a descriptive name, myringitis Primary myringitis must be an uncommon disease, and such conditions as interlamellary abscesses described by Politzer would be considered by Ruttin[9] as extensions from middle ear infection and situated in a small space which he has described within the structure of the tympanic membrane—a miniature bursa of the handle of the malleus

Herpes zoster oticus, a rare condition, provides another possible cause of ear pain, and perhaps it is but the severe manifestation of a syndrome which may exhibit polyneuritis meatus auditorii interni, or even so-called banal facial paresis alone[10]

In conclusion, primary otitic erysipelas should be mentioned In women the close fitting hat may be the predisposing cause The external meatus, the auricle and periauricular area may all be involved In this disease, when a large blood-clot filled bulla of the deep meatus obscures the drumhead, one might be tempted to diagnose an acute middle ear attack as the origin To open the deeply situated bulla would be permissible, but the result of an incision of the drumhead under such conditions might be far too unpleasant to contemplate

SUB-ACUTE OTITIS MEDIA

By

A LOWNDES YATES, M D, F R C S Ed

ASSISTANT SURGEON FOR DISEASES OF THE EAR, NOSE AND THROAT TO THE ROYAL INFIRMARY AND TO THE CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL

Inflammation in the middle ear is always secondary to infection of the nasopharynx, and like the latter is always sub acute in its beginning It is the obstruction of the Eustachian tube which enhances the acuity of the inflammation and leads to the production of acute otitis media

In acute otitis media, the immediate problem which confronts the surgeon is the potential danger to the patient's life The occurrence of intracranial complications is circumvented by a myringotomy when the inflammation has not spread beyond the confines of the middle ear, or by a mastoid operation when the well known signs of mastoiditis are exhibited. After the drainage of the pus has been established the case becomes one of sub-acute otitis media, and the main problem is the conservation of the patient's hearing

Sub acute otitis media differs from the acute variety in the fact that the Eustachian tube is partially patent and that the pus drains down it The acuity of the inflammation is generally in proportion to the degree of obstruction of the tube

SUB ACUTE OTITIS MEDIA IN CHILDREN

This is characterized by recurrent attacks of evanescent pain in which there may be slight discomfort when *the child presses his mastoid* against the surgeon's thumb and by a transient bulging of the membrane coincident with periods of pain The alteration in the hearing is similar to that found in acute otitis media after a myringotomy or spontaneous perforation and is believed to be due to oedema of the mucous membrane covering the round and oval windows If the diminution of the hearing power is maintained after the period of pain

* Read in opening a discussion in the Section of Oto-Rhino Laryngology at the Annual Meeting of the Public Medical Association, Eastbourne 1931

has passed or when the drumhead is no longer out-placed, it is a sign of bad prognosis A graph of the most usual form of alteration of the hearing is shown in Fig 1 In this the hearing of the middle tones is nearly normal and there is diminution of the acuity of hearing of the lowest and the highest notes.

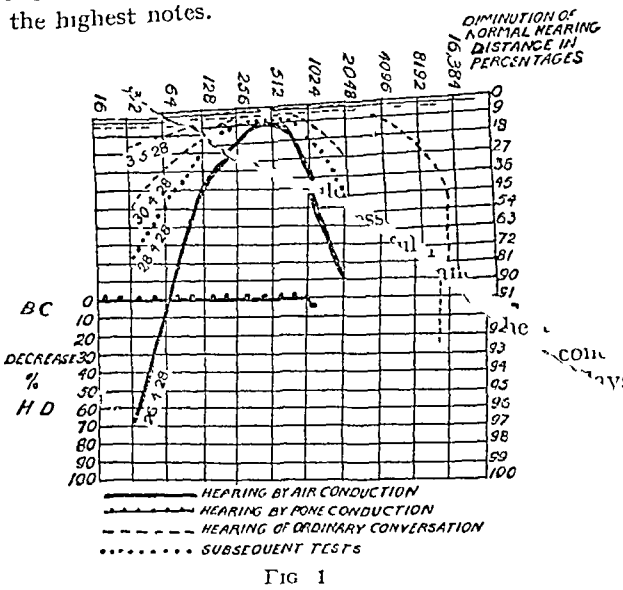

Fig 1

When this graph is found, attention should be focused on the nasopharynx and any adenoids should be removed, while sinuses suspected of infection are washed out In the mildest of the cases this is all that will be necessary, but in the more severe a myringotomy should be performed and the incision should slit the membrane for nearly its whole length behind and parallel with the handle of the malleus

After the myringotomy and the removal of the adenoids the patient should be kept in bed for a few days In cases of sub acute or of acute otitis media, deafness will follow if the inflammatory condition is maintained for a long period An increasing deafness after myringotomy will warrant the performance of a mastoid operation, particularly if the deafness is bilateral In general, I believe it to be true that if discharge persists in the middle ear for longer than six weeks and during this period is accompanied by deafness, then we cannot guarantee that the deafness will entirely disappear, although in fortunate cases it may do so

All modern operations on the mastoid of the child are based on that of Schwartze, which needs no modification if the cavity left by exenteration of the mastoid cells is small In larger cavities or in those which are exceptionlly deep and narrow, the muscle graft or periosteal graft can advantageously be used to fill the cavity When the cavity in the bone is very large, it will take so long to heal by granulation that meatal drainage by the Kuster method may be indicated, for in this method the cavity is healed by growth of skin upon the bone In our decision on the need for mastoid drainage, and in our conduct of the after-treatment, one point is specially worthy of attention This is concerned with the fact that the deafness which results from the inflammatory conditions of the middle ear does not display its full severity in the early stages In the fibrotic change which follows sustained inflammatory states of the mucosa of the middle ear, there is but little deafness till the fibrous tissue has contracted In our decision whether an operation is demanded in order to conserve the hearing in a young child suffering from sub acute otitis, we have to draw on our experience gained from those children who were old enough to co operate with the surgeon sufficiently to enable him to carry out exact tests of the hearing

The type of sub-acute otitis media which we have considered is that most commonly found in children It is of prime importance, for sub-acute otitis media does not reveal itself by the dramatic symptoms of acute otitis but requires more subtle means of diagnosis That the symptoms are not obvious does not imply that the condition is not serious Sub acute otitis media is probably the cause of a high proportion of the deafness met with in adult life Only by basing our treatment on the type and degree of alteration of the hearing can we deal with the problems met with in this condition, and only by a recognition of the danger to the hearing that the maintenance of the low-grade inflammation carries with it can we guard the child against the lack of earning power due to deafness in his adult life.

Sub acute Otitis Media in the Adult

In adults we meet with two varieties of case, the [illegible] in which the sub acute condition is of recent origin [illegible] is similar in all respects to that of children, the other in which the inflammation is maintained and, if undiagnosed [illegible] size, consequently it is in its early stages, leads to irremediable [illegible] as fibrosis This maintained otitis is met with in [illegible] deafness, until atrophic forms which bear distinct relief [illegible] trophic and hypertrophic similar states of inflammation [illegible] semblances to [illegible] nose.

Hypertrophic Form of Sub-acute Otitis Media

The history is generally that of deafness which [illegible] early stages is extremely variable from day to day [illegible] may be periodical attacks of aural pain which is [illegible] cent as the deafness Later, attacks of pain become [illegible] quent and finally they cease The deafness [illegible] intermittent and becomes continuous, and, if the [illegible] observant, he will note that in the early stages [illegible] the sounds around him with but little diminution [illegible] has considerable difficulty in understanding conversation [illegible] because the words run into one another. (Confluent speech) When there is difficulty in understanding speech although the voice is plainly audible, I class the deafness as "uncompensated," in contradistinction to the deafness which is compensated, in which the words are intelligible if the sound of the voice is plainly heard

Examination —The graph of hearing in these cases shows the same features as that of sub acute otitis media in the child (See Fig 1) In the later cases the deafness is generally more marked, the increase being steadily continuous, though slow. In the early cases, the translucency of the tympanic membrane is diminished and in the later cases it may be opaque The cone of light may be displaced and the whole membrane gives the appearance of being less concave than normally This is indeed the case and the concavity can be restored by raising the pressure in the meatus with a Siegle's speculum On raising of the pressure we may sometimes see a wave of fluid pass from one part of the tympanic cavity to another. If by the examination the presence of fluid in the middle ear is demonstrated or suspected, the next step is to cocain the nose and to obtain a sample of the contents of the Eustachian tube for microscopical examination This is aspirated from the Eustachian tube, or middle-ear, by passing a tympanic catheter along the lumen of a Eustachian catheter, so causing it to enter and pass along the lumen of the Eustachian tube, and then applying suction to it with a syringe On microscopical examination it is seen that the contents of the middle ear consist of mucus in which are leucocytes together with some micro-organisms, most of which are intracellular The slide is kept on a warm stage The leucocytes and micro organisms tend to disappear and the time they take to do so may be of service in determining the line of treatment or the prognosis.

Cases fall into the following main groups:

1. Those in which the micro-organisms and leucocytes disappear within an hour and a half. In the majority of these the infection of the middle-ear clears up spontaneously when the parent source of sepsis in the nose or nasopharynx has been remedied.

2. Those in which the leucocytes and micro-organisms disappear within three hours. The majority of these get well on removal of the parent source of sepsis and on repeated aspiration of the tube.

3. Those in which the leucocytes disappear but in which the micro-organisms remain within the fluid. In some cases these micro-organisms can be cultivated and in others they are dead. Failure of disappearance of the micro-organisms is a point of bad prognosis. This last group must not be confused with the effects of dilution of the mucus with saline. If mucus from a case in the first group, in which the micro-organisms disappear spontaneously in ninety minutes, is dissolved in saline, the leucocytes will disappear, but their bactericidal ferments are too dilute to kill the micro-organisms which may occasionally flourish in this diluted medium which before dilution was efficiently bactericidal.

A diagnosis by microscopy of these fluids cannot form part of our information in the examination of these cases, but if occasionally carried it probably enables us to recognize and treat certain cases with increased efficiency.

Malignant Disease.—The infection of the Eustachian tube and middle-ear is never primary but always secondary to some other infection in the nose or nasopharynx. This area should always be found, and if the infection is within a sinus this sinus should be washed out under cocaine anaesthesia, either alone or combined with nitrous oxide. The material for washing may well be liquid paraffin, as this does not dilute the bactericidal substances. These washings will be repeated twice a week until either the sinus contents are no longer purulent or until the failure to resolve with washings once more indicates the need of surgical drainage of the sinus. During the same visit, when the sinus is washed out, the Eustachian tube is aspirated with a tympanic catheter. The progress of the hearing must be watched with special tests and indicated on the graph or quantitative record of the hearing. In cases which are not progressing favourably and in which the infected mucus cannot escape from the middle-ear as quickly as it is secreted, a myringotomy will have to be performed. The normal, or, in fact, the only, natural means of emptying the middle-ear is by the action of the ciliated epithelium which is chiefly active in the Eustachian tube. If the ciliated epithelium has been destroyed, the Eustachian tube is generally patent, and the ear can be spontaneously inflated by Valsalva's method. If this is the case, a myringotomy may be performed, and the incision should be so planned that the middle-ear is emptied of its contents through the incision on inflation. The myringotomy will tend to close, but this may be in part prevented by the use of drops of liquid paraffin and by separating the edges of the wound each day by aspiration with a Siegle's speculum. It must be admitted that the greater the hypertrophy of the mucous membrane of the middle-ear, the greater is the tendency of the myringotomy to close. If the myringotomy wound closes and repeated aspiration fails to cure the case, the question of a mastoid operation or meatal drainage will be considered only in those cases in which the retention of the maximum degree of hearing is of real importance and the condition has not advanced beyond the point at which the subsequent contraction of the fibrous tissue in the tympanic mucous membrane will inevitably cause deafness.

Rutt

Atrophic Form of Sub-acute Otitis Media

Isolated cases in this group appear generally to trace the destruction of their deafness to an attack of influenza. Influenza appears to be a generic term for all forms of acute nasal inflammation in which the infection is by micro-organisms which do not produce pus, that is to say, they do not call forth leucocytes by their chemical attraction. The type of micro-organisms which produce attacks of influenza appear to be those for which an antiserum can be elaborated in the circulating serum. The manufacture of this serum is accompanied by fever, and when the temperature falls it may be because the immunity is now established. The fall of fever may, however, indicate that the infection has been partly cured by some local application. If the micro-organisms are thus artificially destroyed within the nose, they still survive within the ear, and they are present in too small a quantity to produce immunity and bactericidal substances, and so they live and flourish in the tympanum.

If a study is made of each case of influenza which is accompanied by deafness, we find that after the attack the nasal mucus contains a quantity of desquamated epithelium. Similar desquamated cells are characteristic of the contents of the tympanic mucus in the atrophic type of sub-acute otitis media. In such cases the history differs little from that of the hypertrophic form of the condition.

The hearing in the early stages of this complaint shows the changes which are characteristic of the sub-acute otitis media of children. (See Fig. 1.) In the chronic cases, which are those we generally see, there is a steadily progressive deafness which finally becomes indistinguishable from that associated with otosclerosis. The graph of such a case is shown in Fig. 2.

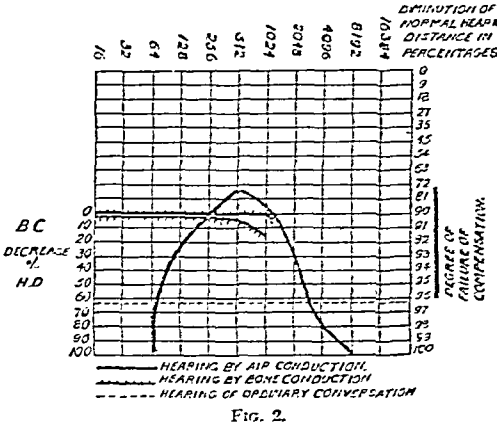

Fig. 2.

On inspection, the tympanic membrane is more translucent than the normal, and, in fact, may nearly be transparent. The inner tympanic wall, denuded of its epithelium, shines red through the transparent drumhead. Sometimes the middle-ear is nearly dry, and in other cases it is filled with mucus in which bubbles may be clearly visible. This stage of the condition is as incurable as otosclerosis, which it resembles closely. Unlike otosclerosis, however, this condition was at one time eminently curable, but because in its period of curability it was symptomless, it attracted no attention. If after an attack of influenza the ear is inspected, as a part of the routine examination, with an electrically illuminated Siegle's speculum, in a few cases fluid with bubbles in it will be noticed in the middle-ear. Such patients should receive an aspiration of their Eustachian tubes, and their return to aural health should be supervised both by examination of the secretions of the nose or ear and by the record of the hearing in some graphic manner such as will display the rate of its return to normal. In watching such patients we discover that the majority

recover aural health spontaneously. It is the recognition of those who do not thus recover aural health which is important, for a proportion of them will drift on to deafness, which is as preventable in its early stages as it is irremediable in the stage in which we generally see it.

The conditions which tend to cause the maintenance of the state of inflammation should be kept in mind. I will not deal with them, for, except for the occasional occurrence of a sinusitis, or a tonsillitis, they are the province of the physicians, who tell us that anaemias, liver deficiencies, constipation, acidosis, and the presence of a toxic focus are the common causes of the failure of establishment of immunity from an infection.

THE USES AND MISUSES OF VACCINES*

BY

J. A. BRAXTON HICKS, M.D., M.R.C.P., D.P.H.

READER IN PATHOLOGY, LONDON UNIVERSITY; DIRECTOR OF LABORATORIES, WESTMINSTER HOSPITAL

With the introduction of vaccine therapy as a general therapeutic remedy by Wright and his school we witnessed what so often occurs when a good remedy has bad or indifferent advocates. Many of those who in the early days of vaccine therapy "used vaccines" had little or no knowledge of the remedy they proposed to use, nor did they attempt to study the principles of an antigen-forming antibody as exemplified by the injection of an antigen (or vaccine) into their patient. They merely administered the vaccine by rule of thumb at stated intervals, and hoped for the best. It never seemed to occur to those who thus misused vaccines that they were not even prepared to allow to a foreign protein (such as a vaccine undoubtedly is) the same vagaries as they would to a drug such as digitalis—namely, personal idiosyncrasies. It is therefore not to be wondered at that vaccine therapy, after a certain period of great popularity, fell under a cloud and was looked at askance. From being a "cure-all" it became a "no-good-at-all" in the eyes and teaching of many, and only of recent years has a more sane and reasonable view been adopted as to the place of vaccines in the therapeutic armamentarium. Even nowadays one has recently seen correspondence on such a subject as "Why do not pathologists adopt a standard initial dose?" Why does the *Pharmacopoeia* lay down the dose of iodides within the region of 5 to 20 grains according to the salt used; and have those practitioners who want a standard dose ever heard of iodism?

Generally speaking, vaccines can be used where time is not of great urgency, and where an active immunity lasting for some time can be aimed at. Antiserums, on the other hand, are remedies for urgency, and the production of passive, and usually very temporary, immunity only. Thus vaccine therapy is of the greatest use in prophylaxis, and it is probable that the public will never realize the debt it owes to T.A.B. prophylactic inoculation during the late war.

While it is obvious that for prophylactic inoculation stock vaccines must be used, I am strongly of opinion that where there is a chronic bacterial infection, the organism of which is known and can be obtained from the lesion, then an autogenous vaccine is the best. I have come across certain cases that have failed on an autogenous vaccine, and then have cleared up on a stock vaccine of that particular organism; but such cases are in my experience rare.

Detoxicated vaccines are in my opinion useless as specific remedies, and whatever good may be obtained from their exhibition is merely the result of foreign protein shock. In fact, one has obtained as good results in certain gonococcal cases from giving detoxicated T.A.B. as from giving detoxicated gonococcal vaccines.

* An abstract of a lecture to the Post-Graduate Section of the Hertfordshire and West Herts Medical Society.

Type of Case Suitable for Vaccines

As regards the type of case suitable for vaccines, I think success is more likely with young people than with old, and the nearer one gets to the age of 50 the less likely one is to have success. After 50 I am always chary of advising a vaccine, and in my opinion the lack of success with colon bacilluria in elderly women is due to "anno Domini." Even in this type of case one sometimes seems to get remarkable results, for some women after the menopause seem to take a new lease of life, and once more I would emphasize the advisability of autogenous *coli* over stock vaccines.

In many types of infection I really think the pathologist or bacteriologist should see the case it is proposed to treat. It may be argued that this involves an additional fee and expense, and that a bacteriologist is no clinician. While these things may be true in theory, in practice a bacteriologist who is accustomed to treat cases with vaccines is apt to know more about the chances of success with any given case. While I am no advocate of retrograde medicine, there is much to be said in practice for our forebears' ideas of "types" and "diatheses," and this applies equally in vaccine therapy.

Patients with a high temperature are unsuitable for vaccine therapy; and in acute infections it is unwise to give vaccines. Here again one comes across notable exceptions; for I well remember one of my laboratory clerks, desperately ill with a streptococcal arm, who seemed to pick up (and finally recovered) from the first administration of an autogenous vaccine. Anyway, should you decide to give an acute infection a vaccine, start with almost incredibly small doses, and increase them by doubled amounts daily until a reaction is obtained.

Patients with conditions of great chronicity, such as chronic sinuses, particularly if there is any cause for the chronic sinus, such as a buried stitch, a piece of dead bone, etc., are quite hopeless until the cause has been removed, then healing perchance may be accelerated by the administration of a suitable vaccine. During the war there were some types of mind that insisted on requesting the bacteriologist to prepare a vaccine for chronic sinuses at the bottom of which were huge sequestra caused by comminuted fracture from shrapnel. The only legitimate reason for putting such a case on a vaccine is to increase its bacterial resistance pending an amputation or removal of sequestrum, and this may be done with benefit in such cases. In the war, I am afraid, it was sometimes asked for under the peculiar impression that the vaccine would unaided heal the sinus and remove the sequestrum. Very chronic colon bacillurias, again, are quite unsatisfactory cases, for the time to put a patient on a *coli* vaccine is in the acute stage, as soon as or, in some cases where the fever is not severe, before the temperature falls. So often I think one is inclined to give the urinary antiseptics first and the vaccines as a last resource. This I believe to be wrong, for I hold that all the "shots in the locker" should be brought to bear on the enemy, and that both vaccine and urinary antiseptics should be given. Do not let us regard a vaccine as a thing apart from ordinary therapy, but as a part of ordinary therapy—another weapon to be used in suitable cases along with drugs and surgical operations.

Dosage

And now we come to dosage. I have made a few observations on those who desire a standard initial dose and so forth. I believe from the nature of a vaccine such a thing to be impossible. I would go further and say that

every case you attempt to treat with a vaccine is in the nature of a personal experiment on your particular patient When I am asked to treat a case, or advise on a case I always try to insist that the patient be made to understand that one is about to try and see whether or not he will form curative bodies as the result of the injections The patient, as a rule, readily appreciates the idea, and co-operates in such details as letting you know about any feelings of malaise, local soreness, etc , after an injection Explain before the start that you may fail because his tissues may possibly fail He readily appreciates from common knowledge of drugs in general that drugs occasionally are not successful in producing the desired effect, and so he is not disgruntled to the same degree at a failure of a vaccine to stimulate his tissues to cure him

I am often asked how to judge the interval between the dose As one of the first principles of vaccine therapy, I may say there is no such thing as a rule-of thumb interval While a general rule is that as you increase the dose you increase the interval, it is most important to recognize from the beginning that each case must be treated strictly on its merits

In prophylaxis one gives one to four doses at more or less fixed intervals, but even here one sometimes finds undue susceptibility to the first or subsequent doses, and it is most harmful to proceed to inject the case again at the prescribed rule of thumb interval Wait until the reaction has passed off and then proceed

In therapy there are two main schools one recommends a large dose at fairly long intervals, the other small doses at frequent intervals I myself prefer to give small doses at frequent intervals in the early stages, gradually lengthening the intervals and increasing the doses as tolerance appears to increase

There are certain advantages in this latter method, in that one never should get an unduly severe reaction How does one tell when a patient gets a reaction? Apart from general malaise, etc , which one aims at avoiding as far as possible, it is the site of injection that tells this At the site of subcutaneous injection there will almost invariably be a red mark This follows any injection of foreign protein, but if in addition there is local induration, this is a reaction The amount of the induration is a measure of the reaction

Therefore whatever vaccine is being administered, start with a low dose and look for this induration If it is absent, I repeat with a larger dose next day, and so on daily until a reaction appears When a reaction appears, wait until the induration has almost gone, and repeat the same dose that produced the original reaction If this dose produces a trivial or no reaction a further increase may be essayed in the dosage, again watching for the reaction Should reaction occur, observe the same rules as have been formerly laid down, and do not yet increase the dose *Only increase the dose when you are sure that little or no induration has occurred*

You will find that individual cases vary enormously In *B coli* or staphylococcal cases, starting as I do with 25 to 50 millions it may be found that the first reaction occurs with 250 millions or even more, whereas in some cases one cannot go higher than 50 to 100 millions I am convinced that many of the failures of vaccine therapy have been due to the lack of appreciation of this extreme variability in the sensitiveness of the individual to his vaccine

Vaccine Therapy

Tuberculosis —As regards tuberculosis, I only use old tuberculin (both bovine and human strains) and similar preparations of bacillary emulsion (B E) I prefer the old tuberculin for treatment, though this is not in accord with all authorities As an initial dose, in both preparations I use a dilution of 0 002 gram per c cm , which works out to about 0 0001 per minim (taking 1 c cm as 20 minims) I start with 1 minim and increase the dose by 1 minim a day until a reaction occurs, and then proceed according to the lines previously mentioned As the doses get larger (and you may get up to even 1/2 to 1 c cm of the undiluted tuberculin) so, of course, you will find the intervals have to be much increased I regard phthisis, even apyrexial cases, as quite unsuitable for tuberculin treatment, at any rate outside a sanatorium, and I think the bacillary emulsion (either bovine, human, or a mixture) the preparation to be used for this type of case Most of the cases of renal and pelvical tuberculosis that one encounters are too advanced or quite unsuitable for vaccine therapy, though early tuberculosis of the testicle may afford some hope of success I have seen quite remarkable results in tuberculous pleurisy and in peritonitis of the non-adhesive type Certain eye and skin conditions and early tuberculous joints give a percentage of success, but the best cases to deal with in my opinion are tuberculous glands In treating these tuberculous conditions do not hesitate to employ or have employed any other beneficial remedy known to give relief—thus, for example, see that an early tuberculous joint is kept at rest

Gonorrhoea —In gonococcal infections I have never been in the least impressed with the results of vaccines in the acute stages, even though on many occasions I have used an autogenous vaccine In the chronic stages of prostatitis I have used stock vaccines without great success, but I think a mixture of stock vaccine plus those organisms of secondary infection which always occur and which can be obtained in the secretion after careful prostatic massage, are often very helpful It is these organisms of secondary infections that keep up the trouble, and not the gonococcus In women I do not give vaccines, because, candidly, I am afraid of possibly producing a violent reaction, with spread to the tubes and peritoneum I have seen it occur more than once, and I do not think it worth the risk for the problematical benefit that may accrue

Chronic Catarrh —In the chronic catarrhal states, including bronchitis and asthma of bacterial origin, one is up against many difficulties For instance, if there is any nasal or sinus condition present, that must be treated by suitable means It is useless to treat a condition of chronic nasal catarrh associated with a badly deflected septum or nasal polypi with a vaccine, but I have been invited to do so more than once Hence, have such conditions carefully excluded by a competent specialist Similarly, in an aged patient with emphysema and purulent bronchitis of considerable chronicity, the real trouble is that his lungs and bronchioles have lost their elasticity, and purulent secretion collects in the dilated bronchioles A vaccine will not restore his elasticity nor close his dilated bronchioles, and I regard a vaccine as useless in this type of case In patients who suffer from recurrent colds, particularly the seasonal ones of autumn and spring, much can be done by autogenous vaccines in the former and stock vaccines given prophylactically in the latter case Again I would remind you not to neglect auxiliary methods of treatment and I always advise that cases of chronic nasal catarrh should use a glass nasal douche (never a syringe) with some mild antiseptic lotion (such as glycerin thymol co *B P C*) night and morning, combined with the injections of vaccine After all, one is dealing with a susceptible and damaged mucosa and if it is to recover it is as well to remove the products of inflammation and catarrh as often as possible One never quibbles about washing away the products of inflammation from wounds, so why avoid the obvious? I have never seen Eustachian tube trouble follow from douching, provided a syringe is not used.

Vaccines in Dental Practice

I suppose you have wondered why I have not mentioned the question of vaccines in dental practice, and the pros and cons of vaccines in pyorrhoea and apical infections. The subject is too difficult, and to a certain extent too controversial, to deal with in a brief lecture, but I maintain that, given co-operation between the bacteriologist and a dental surgeon, who is also an expert in interpreting *x*-rays of the teeth, a great deal of most valuable salvage work can be done. Some teeth have to come out, others may be salvaged, and it is the expert dentist, accustomed to working with a bacteriologist, who, in my opinion, can do such useful work.

Intravenous Method of giving Vaccines

All my remarks so far have referred to subcutaneous administration of vaccines, but to conclude my lecture I would mention one method of giving vaccines which may or may not be a method of producing a non-specific protein shock. I refer to the intravenous method of giving vaccines, and I hold that in many cases one is certainly giving a specific protein. One knows that large doses of T.A.B. have been given intravenously in cases of general paralysis of the insane, asthma, etc., also peptone solutions, and this, of course, is non-specific protein therapy. I have, however, had many cases of arthritis, in particular where there seemed to be definite foci of infection (either dental, intestinal, etc.), that have responded in a most striking manner to autogenous intravenous treatment when the subcutaneous method had failed. It is necessary to add a few words of caution about the intravenous administration of vaccines. The initial dose must be small, at least half the dose that I should commence with in subcutaneous injection. The patient must be warned that he or she may feel quite uncomfortable about an hour or so after the injection, the symptoms being headache, shivering, and pains all over. Aspirin, bed, and hot bottles usually quickly ameliorate these symptoms, and after a fairly profuse sweating the patient recovers in a few hours, and feels none the worse, though possibly a little limp. Occasionally these symptoms may be very severe, but I assure you that, however severe, there is no cause for alarm. In extreme cases the reaction may last two to three days, and, although your patient may reproach you for causing such inconvenience, it is in these cases that I have seen the best results.

I had one patient with arthritis who, after each injection, had the most violent reaction ; yet so impressed was she by the obvious improvement that followed each bout that she continued the treatment till a free movement of her joints was obtained, and all that remained was the existing bony and joint changes prior to treatment. I may add that she is now playing a very useful game of golf, and, while regarding me as her benefactor, does not properly apportion the credit due to herself for sticking it out.

Though one may get these violent reactions in susceptible cases, there is fortunately no cause for alarm, and the symptoms need only be treated. Once you have adjusted the dose you will find that on increasing your dosage the subsequent reactions tend to be of a trivial nature, and that the case I have just quoted is the exception rather than the rule.

THE ORGANIZATION OF TREATMENT FOR INFANTILE PARALYSIS*

BY

G. MURRAY LEVICK, M.R.C.S., L.R.C.P.

CONSULTANT FOR PHYSICAL TREATMENT, EAST SUSSEX C.C.; MEDICAL DIRECTOR, HERITAGE CRAFT SCHOOLS; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN

The organization of treatment for infantile paralysis may be divided under two distinct headings, the first dealing with the acute attack, the second with the after-effects of the attack. The object of this paper is to explain that the scope and variety of the special technique involved in each case are so wide that organization becomes a necessity.

Treatment of the acute attack is of importance because it may greatly influence the subsequent degree of disability. This is a point on which emphasis should be laid, as it is too little realized. Unfortunately, owing to the infrequency of its occurrence and the unexpected way in which single cases or epidemics occur in out-of-the-way places, the acute attack often goes undiagnosed until after its subsidence; the signs of paralysis follow what was thought to be a case of influenza or something of that sort, and are not discovered until the patient is allowed to get up.

In the orthopaedic scheme of the East Sussex County Council, we have complete preparations for acting promptly at the onset of the disease, but we are, of course, dependent upon the alertness and co-operation of the general practitioners in every case.

With regard to early diagnosis I would emphasize the importance of examination for muscular tenderness in all cases of acute pyrexia without obvious cause. A rapid passage of the hands over the four limbs and squeezing of the various muscle groups can be carried out in a couple of minutes. If acute tenderness is noted and for this and other reasons suspicion is aroused as to the diagnosis of acute anterior poliomyelitis, prompt investigation of any case rising in East Sussex may be secured by telephoning to the county M.O.H., Dr. Ashleigh Glegg at Lewes. If it is considered desirable, Dr. Glegg will then ring me up and I will proceed to the spot to meet the practitioner in consultation, with all dispatch.

By arrangement with the Lister Institute I have a supply of the new anterior poliomyelitis antitoxin always in readiness and, if we make the diagnosis, can administer it at once. This is considered to be the best procedure, but in case I might be unavailable with sufficient dispatch, I have in cold storage a supply at the Girls' Heritage School, Chailey, so that the R.M.O. can administer it without waiting for me. It should be given partly intrathecally and partly intravenously. For a favourable prognosis, the serum should be given, at any rate, in the first few hours of the attack, but in view of the pathological picture, it appears to me worth while to administer it at any time during the persistence of the pyrexia. Apart from this antitoxic treatment, special orthopaedic measures are important.

The correct posturing of the affected parts *at the very outset of the disease* is of paramount importance, and this should be secured without pressure from bandages, which tends to increase the atrophy of the affected muscles. The lumbar puncture carried out in the administration of the antitoxin affords an opportunity for withdrawing cerebro-spinal fluid to relieve pressure, if desirable. The posturing of the limbs by the method of slinging, which I will shortly describe, should be carried out without delay as soon as the muscular pain has departed. There is no need to wait until tenderness to pressure has gone.

* Read in opening a discussion in the Section of Public Health at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

The pathology of the disease being outside the scope of this paper, I will only allude to it so far as necessary in dealing with the after-treatment.

We must bear in mind that in the majority of cases, although there is complete obliteration of anterior horn cells to a variable extent, many of these are frequently put out of action by a disturbance which falls short of complete destruction. This disturbance may be the result of the toxin or of pressure from engorgement and extravasation of blood in the anterior cornua. After a time, many of these cells may recover but their axons may have perished. A year or more may elapse during which regeneration of these axons is taking place. If the muscles are ill treated or, in many cases, if they receive no treatment, they may lose their contractility, so that little or no muscular response can be elicited when the regenerated axons reach their destination. Therefore measures should be carried out with a view to preserving the contractility of all the affected muscles for at least a year before hope of recovery is abandoned.

These measures are partly the correct posturing of the affected groups, while protecting them from pressure, and partly other measures. It is, however, important to mention that the patient should be placed in the hands of those who are specially qualified to treat such cases. Properly administered electrical treatment is of great assistance in maintaining the contractility and nutrition of the paralysed muscles, but if improperly administered much harm may be done and is done, leading to opinions adverse to electrical treatment which are quite erroneous.

It is a surprising fact that physical treatment is not included in the examinations or curriculum of the medical student, consequently it is carried on as a general rule without the competent supervision of medical men. This supervision is needed not only to direct the treatment but to decide when it is needed and when it is no longer of any use. Much time and expense are wasted on the electrical treatment of muscles long after an electrologist with the requisite knowledge would have explained that recovery of function could not take place.

One of the greatest yet commonest of mistakes in giving electrical treatment for anterior poliomyelitis is excessive faradic stimulation. In fact, it should never be administered in the early stages of nerve recovery, when the faradic response is just returning. Only the single stimulus of the interrupted galvanic current should be used at this time. Massage, a very important part of the treatment, is less likely to cause damage, but even here harm may be done by deep effleurage, which is in my opinion a mistaken form of treatment for almost any condition.

There is yet another aspect of this disease which calls for special mention. We should never forget that the acute attack is a severe shock to the nervous system as a whole, and every patient who has been through it is left in a state of profound general neurasthenia demanding prolonged rest and constitutional treatment. I am convinced that if these facts were more generally realized the [illegible]ent of recovery in many cases would be greatly [illegible]d. For this reason open-air nursing and helio- should always be carried out and continued for [illegible]ths or even years, according to the severity of

[illegible]apy is of decided value, though its effect vi[illegible]y according to the type of radiation and the met[illegible]oyed. At Chailey we have fourteen complete sets of la[illegible] each set being a complete unit for the production of the whole solar spectrum. As a result of comparative tests carried out at St. Thomas's Hospital and the Victoria Hospital for Children, I have not installed any carbon arc lamps at Chailey, and have in fact ceased to use them anywhere. In their place I use a battery of four carbon filament lamps for the production of visible and infra-red rays and one mercury vapour tube for the ultra-violet rays, in each unit. The ultra-violet radiation can thus be adjusted to the tolerance of each patient, separately from the longer rays, which is very important. As a result of experiment with intense visible radiation I now attach great importance to this part of the spectrum.

This general radiation of the body is, of course, a measure for improving the general nutrition and recuperative powers of the patient. It is, I can assure you, a treatment of very high value. Its effect in the treatment of debilitated patients can hardly be overestimated. A couple of years ago, an adverse report on the subject of artificial heliotherapy was published by the Medical Research Council. You will be well advised to pay no attention to this astonishing document. It is only fair to the Medical Research Council's own special committee on light to say that this publication was issued without its authority.

For local treatment, I have for many years, as a routine, irradiated the paretic muscles with intense red light. The scientific rationale of this treatment I explained in a paper read before the International Congress of Radiology in London in July, 1925, and published in the *British Journal of Radiology* of May, 1926, and in a paper on the treatment of infantile paralysis published in the *Lancet* of August 15th, 1925.

Postural treatment is another measure demanding special care. When any of the trunk muscles are affected it may be needful to carry out prolonged treatment in the recumbent position to prevent the tragic spinal and costal deformities so often seen in these cases. Sometimes this recumbency should be maintained for several years in the case of growing children. It is the only way to prevent very serious spinal deformity if the abdominal or erector spinae muscles are affected to any practical extent. For such cases open-air nursing all the year round is very desirable. The patients remain strong, vigorous, and in excellent health if they are kept in the open air, whereas in hospital wards they would become weak. All these matters have been referred to, in order to explain the necessity for organized institutional treatment for infantile paralysis, because the many needs of these patients can be met economically in this way owing to the congregation of a large number of cases.

[Lantern slides were then shown depicting various methods of treatment carried out at Chailey.]

In summing up, it may be reiterated that many cases of infantile paralysis require institutional treatment extending over a number of years. When you come to think of it, this is far from being an unreasonable demand. No one hesitates to provide instruction for children in schools where they are taught lessons hour after hour every day, from the age of 5 until they are 14, therefore it is not asking too much to demand that a growing child, suffering from the effects of infantile paralysis should have daily treatment extending over some years; because this can be obtained concurrently with education at Chailey and other institutions throughout the country, and if the children can live at home many cases can receive this treatment at the out-patient clinics of the county orthopaedic organizations.

The reason that treatment is so important in the case of the growing child is that, as the limbs grow, paretic limb muscles are apt to become shorter than their twins on the opposite side, leading to postural deformity or further weakening by stretching. These affected muscles may need periodical treatment until the patient has ceased to grow. The need for operative treatment is in most cases brought about by lack of, or improper, physical treatment.

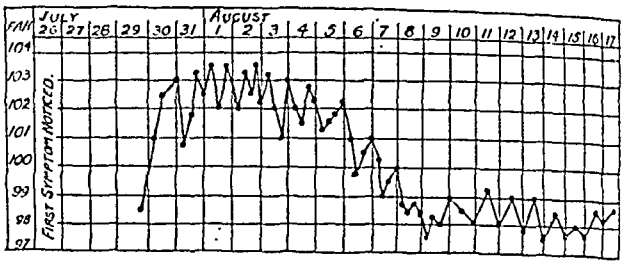
The county orthopaedic organizations are now spreading throughout Great Britain as the result of the original inspiration of Sir Robert Jones. East Sussex has its own county scheme on these lines, with Chailey and its marine hospital at Tidemills as its central hospitals and school, and out-patient clinics at Lewes, East Grinstead, Hailsham, Crowborough, and Burgess Hill, where after-treatment can be given to children discharged to their own homes under medical supervision from Chailey, and children attending these clinics can be admitted to Chailey as occasion demands for hospital treatment. In this way the whole East Sussex area is linked up with its central hospital.

I cannot conclude this paper without reference to the lack of organized treatment for paying patients of small or moderate means. To obtain privately the necessary treatment under the right conditions is impossibly expensive for any but rich people. If those institutions which offer resident treatment for paralysed poor children or adults wish to make their work complete they should certainly make separate provision at a little over cost price for those who can pay only small or moderate fees. The present institutions are unsuited for the children of the upper class, because there they must be educated with those who are by their upbringing and ideas unsuitable for them as companions. A vulgar accent is only one of the drawbacks that arise from such companionship. Only we doctors seem to realize the pitiable circumstances arising so often from lack of sympathy and enterprise in this matter.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

OEDEMA ROUND THE EYES CAUSED BY TRICHINA SPIRALIS



Infection with *Trichina spiralis* in man may produce a variety of clinical pictures. The patient may present a pyrexia with no obvious cause, and enteric fever be simulated; or the fever may be accompanied by severe pains in the limbs and back, so that a diagnosis of acute rheumatism or of influenza may be suggested. But there is another group of cases in which the chief symptom is oedema round the eyes, with no other striking symptom; these cases are usually first seen at ophthalmic hospitals. The following case is an illustration of the last group.

History of the Case

The patient was a female, aged 25, who lives in London and has never been abroad. Her husband is a french-polisher. She was quite well until July 26th, 1931. On that day she awakened with a feeling as though she were about to develop a "cold in the head," and in the afternoon noticed that her eyes seemed rather puffy underneath. On the following day the eyes were much more puffy; she had no other symptoms, and felt well in herself. On July 28th the eyes were almost closed by the swelling, and towards evening she felt tired and depressed, her appetite was lost, and she had slight diarrhoea. She felt thirsty, and drank a large amount of water. On July 29th she was unable to open the eyes on account of the swelling, and during the day vomited on several occasions. In the afternoon the temperature was 98.6°, when she was examined at Mr. G. G. Fenwick's clinic at the Royal Westminster Ophthalmic Hospital. The fundi and ocular movements were normal, and the urine contained no albumin. She was seen by me at the Royal Westminster Ophthalmic Hospital on the following day.

On July 30th the eyes were almost closed by oedema, and they appeared to be unduly prominent. The patient felt ill and sleepy and sick, though she did not vomit on this day. There was no pain or tenderness in any muscle. As the urine did not contain albumin, as the blood pressure was normal, and as the fundi did not present any abnormality, a provisional diagnosis of infection with *Trichina spiralis* was made. A blood examination showed no eosinophilia. The patient was admitted to Charing Cross Hospital for investigation.

On admission in the afternoon of July 30th the temperature was 101.2° (see chart). There was fever for nine days. A

second blood examination made on August 5th (the eleventh day of the illness) revealed a high eosinophilia. The results of several blood counts are shown in the table. The patient vomited twice after admission, on August 2nd and 3rd. No other gastro-intestinal symptoms were noticed. The oedema round the eyes subsided during the first week after admission. At no time was any pain or tenderness noticed anywhere, and the patient made an uneventful recovery.

On August 10th (the sixteenth day of the illness) a small piece of the trapezius muscle was removed by Mr. R. A. Fitzsimmons; to the naked eye this did not present any abnormality, but in teased-out portions of the muscle many embryos of *Trichina spiralis* were clearly visible under the low power of the microscope. These embryos were not encysted, and for some time after the removal of the portion of muscle they were seen to be alive, coiling and uncoiling themselves among the muscle fibres. Under the high power the spiral arrangement of the worms could be clearly seen, as the whole length of the worm could be followed round the spiral by raising and lowering the lens. There appeared to be two and a half or three turns in the spiral. The adult worms were not recovered from the faeces.

The following table shows the blood changes. The total leucocytes varied between 6,000 and 9,000 per c.mm.

	July 30	Aug. 5	Aug. 7	Aug. 10	Aug 12	Aug 17
Neutrophil polymorphs...	78.0	55.5	51.0	46 0	38 0	45 0
Eosinophil polymorphs...	4.0	18.0	14.5	27.0	18 0	13 5
Lymphocytes	7.0	20.5	24.5	18.5	33 5	34.5
Monocytes	10.5	4.5	9.5	8.5	10 0	6.5
Basophils	0.5	1.5	0.5	—	0 5	0 5

Commentary

The following are the interesting features of this case. The first and, for two or three days, the only symptom was oedema round the eyes. There was a high fever which did not appear until five days after the first symptom; at no time was pain felt in the muscles, nor could tenderness be elicited; eosinophilia was absent five days after the first symptom also, but appeared between the fifth and eleventh days. Living embryos of *Trichina spiralis* were found in a piece of muscle on the sixteenth day of the illness.

It is generally assumed that the oedema round the eyes in cases such as this is due to invasion of the muscles round the eyes by the embryo worms. If this is so, it is interesting that neither fever nor eosinophilia appeared until five days had elapsed after the first appearance of swelling round the eyes.

R. A. Hickling, M.D.Cantab., M.R.C.P.,
Assistant Physician, Charing Cross Hospital; Physician, Royal Westminster Ophthalmic Hospital.

Reviews

THE PSYCHONEUROSES

Dr. Millais Culpin has undertaken the by no means easy task of writing *Recent Advances in the Study of the Psychoneuroses*,[1] a book which is an addition to the well-known Recent Advances Series. The author formerly practised as a surgeon, and served as a surgical specialist during the war, at which time he became so impressed by the considerable incidence of psychoneurosis masquerading under the guise of organic disability of one kind or another that he was subsequently led to specialize in a branch of medicine which he felt to be one of fundamental importance. While, however, his professional interest has been deflected from surgery to psychopathology, it is evident that his attitude towards the problems of medicine has undergone no fundamental change, since (like the surgeon) he shows himself in this book to be primarily interested in the practical and clinical aspect of his subject rather than in its theoretical elaborations. Dr. Culpin holds the view, no doubt rightly, that the chief advances in our knowledge of the psychoneuroses have been the direct or indirect result of psycho-analytic discoveries. At the same time it has not been his aim to add to the already numerous expositions of psychoanalysis, and only sufficient reference is made to psychoanalytical principles and practice to make the general theme of this work intelligible, and to bring out their relationship to general medicine.

In the opening chapters it is shown how the great war provided a stimulus to the study of the psychoneuroses, especially since it was recognized that the war cases, though their symptoms were determined largely by immediate influences, offered nothing different from the cases in civil life. In the war patients it was found that a large proportion had a predisposition to psychoneurosis, but unfortunately no figures were available giving the prevalence of predisposition in the general population. Dr. Culpin has endeavoured to fill up this gap in our knowledge, and, together with Dr. May Smith, has investigated, on behalf of the Industrial Health Research Board, the incidence of psychoneurosis in 1,500 employees in various establishments, with a view to ascertaining the number of persons exhibiting psychoneurotic symptoms. The conclusions reached are somewhat disquieting, since it would appear that nearly 50 per cent. of the " normal " individuals examined were found to exhibit psychoneurotic symptoms in a greater or lesser degree. Fortunately it does not follow that nervous symptoms necessarily involve nervous *disability*, for Dr. Culpin found that one establishment had a high incidence of subjects with severe symptoms, and yet had a low absenteeism, in which nervous breakdown played no part. A chapter is devoted to the occupation neuroses, with special reference to telegraphists' cramp and miners' nystagmus. The author makes it evident, as Janet pointed out some thirty years ago, that the motor symptoms in the occupation neuroses should not be considered in isolation, as these are invariably associated with definite, though less evident, psychoneurotic symptoms. The book includes some interesting observations on the conditioned reflex and the physiological concomitants of emotion, and evidence is advanced in favour of the view that physiological disorders such as asthma, exophthalmic goitre, and various visceral disturbances may be the expression of unrecognized anxiety states.

The above outline of the author's treatment of his subject makes it evident that the book includes much that the general practitioner, as well as the psychopathologist, will find both interesting and helpful. Dr. Culpin is not responsible for the last four chapters. Independent contributions are written by Dr. A. R. Redfern on the individual psychology of Adler, and by Dr. James Young on the teaching of Jung. Child psychopathology and the management of a psychotherapeutic clinic are also treated separately by Dr. E. Miller and Dr. J. R. Rees, each of whom has had special experience in the subject upon which he writes. These additional articles are admirably written, and it may certainly be claimed that this book as a whole provides a useful outline of the " recent advances " in a branch of medicine of great social importance.

NOGUCHI THE MAN

Noguchi[2] is the title of a new book by Gustav Eckstein. So interesting a biography of a scientific man has not appeared since Vallery-Radot published his *Vie de Pasteur* in 1900. Dr. Eckstein has written it in a cramped style somewhat resembling that used by Carlyle. It is often ungrammatical, but is admirably suited to the subject, because it was years before Noguchi learned to speak or write even tolerable English, and his letters blend, therefore, admirably with the text of the story. The book is handsomely produced and well printed in sixty-five short chapters. The dates are those of the Japanese era, but in the summary on the dust jacket they appear according to the Christian reckoning. This is a pity, because the dust jacket will soon be destroyed, and the summary should have been printed and bound in with the book.

The story is an extraordinary one, and is well worth reading and thinking about. To the outside world Noguchi has been known as an early worker on snake poisons. These venoms led him to make and study serums with a view to immunity. Serology interested him in syphilis; syphilis led to spirochaetes and spirochaetes to tropical diseases. Perhaps his most important discovery was the relationship of general paralysis and tabes to syphilis. Hitherto he has been known as a skilled and indefatigable worker in the bacteriological laboratories of America and Denmark; but of his human side, of his hopes and fears and early struggles, nothing was known. Dr. Eckstein has made all clear, and has enabled us to form a lifelike picture of Noguchi the man.

Born in 1876 in dire poverty in a remote village in Japan, he was the second child of a drunken father, who deserted his family, and of an illiterate mother, who earned a scanty living by working in the ricefields, and who, later in life, became the village midwife. From her Noguchi received his mental gifts and his healthy body. Throughout his life he reverenced her, but did nothing to help, even in his days of comparative affluence. But she had her reward; for although she could neither read nor write, she knew that her son had won world-wide renown and had added lustre to Japan as a scientific nation. At the age of three years Noguchi was severely burnt while his mother was away at work, and his left arm was permanently crippled. Throughout her life she blamed herself for the accident, which, in reality, was the making of her son. Noguchi remained a peasant, fighting, as he often said, with his fists and not with the sword, as did the Samurai. Lustful, eating and sleeping how and when he could, untidy in his clothes and habits, secretive, servile and yet arrogant, extraordinarily " messy " in his work, he yet achieved great results by sheer pertinacity and a plodding addiction to the particular piece of work he had on hand. Of money and its value he had no sense at all, and like Ralph Bigod, Esq., of

[2] *Noguchi*. By Gustav Eckstein. New York and London: Harper and Bros.; London: H. Hamilton, Ltd. 1931. (Pp. ix + 419; illustrated. 18s. net.)

whom Charles Lamb wrote, he contrived to keep his treasury always empty by acting on the aphorism that "money kept longer than three days stinks." He was consequently always in debt and had no hesitation in borrowing again and again from those who had helped him repeatedly, well knowing that they would never be repaid. It seems to have been impossible to resist his applications when he wanted to go to China.

"The commission refuses to advance passage money. However, that is simple. He hurries to Chiwaki. But, alas the master has no money, has spent all on his marriage. Noguchi is immediately despondent. He is really a pitiful sight to look on. Chiwaki quiets him with telling him that somehow, he, Chiwaki, will find the money. The way Chiwaki finds it is to sell his wife's new bridal kimono. The sailing is for the following morning."

Is it surprising that the lady had no friendly feeling for him afterwards? Outside his laboratory Noguchi was a child, quick to take offence, but equally quick at reconciliation, fond of gambling, and often drinking to excess. Dr. Eckstein gives a picture of this side of him in the following words:

"Sometimes it is necessary to ask Noguchi to watch the boiling rice. Araki does not like to do so but Noguchi is always willing, brings his chair into the kitchen, puts the chair in front of the gas-range and props up his feet and continues to read. Suddenly he turns to Araki. What is the smell? He seems never able to grasp that the smell could come from the burning of the rice that he is watching. Araki snatches the cover off the boiler. Noguchi looks in. He shakes his head. 'Yes, it's gone. We go out to eat.' He always uses the same words and both get their hats, leave the kitchen as it is, go always to the same Japanese restaurant, a cheap place. As soon as the waiter sees who is coming he begins to serve, never asks Noguchi what he wants because Noguchi always wants the same thing. Sometimes Noguchi does not say one word, not even in the beginning for politeness, right away opens his book, puts it next his plate and Araki does not disturb him. Yet Araki cannot help noticing how Noguchi eats, because that is peculiar. He pokes his fork towards his plate, has no idea what he is poking at, but whatever is at the end of the fork he puts into his mouth. And when he is using chopsticks it is remarkable to carry rice with chopsticks from a bowl you do not see."

Dr. Eckstein makes Noguchi and friends tell the story in their own words, and secures a remarkable picture, the picture of a highly gifted child, lovable because he was so irresponsible, who died on May 21st, 1928, at the age of 52.

CLINICAL INTERPRETATION OF LABORATORY FINDINGS

Studies at the bedside and studies in the laboratory have each their part to play in the arts of diagnosis and treatment, and while they are sometimes presented as rivals their true relation is that of mutual helpfulness. It is from this standpoint that Dr. Michael Wohl has written his book, *Bedside Interpretation of Laboratory Findings*.[3] He neither hopes nor attempts to make every practitioner an expert in the more complicated chemical and biological tests, but he urges that at least the more simple investigations should be undertaken by the practitioner, and that certainly the significance of all laboratory reports should be appreciated by the clinician. He therefore includes in his pages many procedures which were among the commonplaces of bedside study before laboratory medicine made its appearance, such, for example, as the microscopical examination of the blood, and the chemical testing of the urine. That such investigations should now be frequently referred to the laboratory is the responsibility of the clinician, and perhaps also of the clinical teacher, and Dr. Wohl wishes to counteract this practice. Here he is supported by the practical and common-sense "Introduction" written by Professor Joseph McFarland, who points out that a personal observation by the physician in charge of the patient is much to be preferred to a "report" from a non-interested observer. He adds, too, the warning that at the best a "report" is not a diagnosis, but only a contribution to a diagnosis, and that, like other observations and conclusions, this also is not infallible.

Dr. Wohl has kept his ambitions steadily in view through all the chapters of his book, and has certainly attained a large measure of success. He speaks from his own experience in relation both to laboratory methods and to clinical meanings, and carefully avoids inflicting on his readers alternatives which are unnecessary, and which are apt, moreover, to be confusing. The practitioner who wants to cultivate a modest measure of personal laboratory work as supplementary to his clinical responsibilities may consult Dr. Wohl's pages with advantage.

MODERN TREATMENT OF NASAL CATARRH

A valuable addition to the Modern Treatment Series has been contributed by Dr. Lowndes Yates on *The Modern Treatment of Nasal Catarrh*.[4] The solution of the many problems which present themselves is sought on strictly scientific lines by an investigation of the underlying pathological and anatomical conditions. Although the book is intended as a guide for the practitioner in the management of this common ailment, it is by no means a mere compilation of current opinions, but includes a large number of original observations, the result of much patient research by the author, who modestly conceals the fact. Dr. Yates has devoted much time and work to the investigation of the pathological changes which occur in the nose and accessory sinuses during and as the result of inflammatory states. He gives a complete account of this work, which provides a solid basis for appropriate treatment. There is in consequence much in this book which cannot be found in the usual works of reference, and it should be useful to the specialist as well as to the general practitioner. The chief lesson which Dr. Yates has to teach is that the best means of treatment are not always operative, and he shows clearly how much harm can be done by an excess of surgical zeal in relieving obstructions and draining infected cavities. The relation between local and general immunity and the occurrence and control of nasal infections has been elaborately studied, and although much remains to be elucidated, the author shows that an important advance has been made towards a proper understanding of these obscure problems. No attempt is made to provide a complete survey on rhinology, but from the angle at which the subject is approached the author has fulfilled his limited task with thoughtfulness and originality. The criticisms we have to make are that there is unnecessary repetition and that there are many long involved sentences unbroken by a comma, both suggesting insufficient revision of the text.

FRENCH CLINICAL LECTURES

A second volume of the Thursday morning lectures at the Charité Hospital, Paris, has been issued under the title of Modern Clinical Questions (second series),[5] with a short introduction by Professor Émile Sergent, in whose department the eighteen lectures have been given by colleagues in other clinics or assistants at the Charité, and they represent the trend of modern French medicine. Two lectures on asthma give a good account of the subject from certain special points of view. Dr. Haibe of Namur considers

[3] *Bedside Interpretation of Laboratory Findings.* By Michael G. Wohl, M.D. With an introduction by Joseph McFarland, M.D., S.D. London: H. Kimpton. 1931. (Pp. 321; 133 figures. 25s. net.)

[4] *The Modern Treatment of Nasal Catarrh.* By A. Lowndes Yates, M.D., F.R.C.S.Edin. The Modern Treatment Series. London: J. Cape. 1931. (Pp. 160. 5s. net.)

[5] *Questions Cliniques d'Actualité.* 2e série. Paris: Masson et Cie. 1930. (Pp. 343; illustrated. 45 fr.)

bronchial asthma in adults as due to bacterial antigens, and he claims 90 to 95 per cent of cures by vaccine therapy. Dr E. Lesné, dealing with this disease in childhood, is not so optimistic, and he gives a well-balanced account of the special features of the disorder in this period of life. Dr R. Mignot deals with the use of insulin in maladies other than diabetes, and he produces a surprisingly long list of suitable types of treatment. These examples serve to indicate the scope of the book, which well carries out the purpose of introducing these well-known lectures to an even larger audience than can find their way to the famous amphitheatre.

In Medical and Surgical Actualities[a] the younger generation of the medical staff of the University of Marseilles have collected sixteen of their clinical lectures, very much in the same fashion as have their Parisian colleagues. An account of the anaemias of early infancy by Dr. G. Sesques, and a critical review on the subject of hydronephrosis by Dr. C. Lahayville, are among the best of the contributions, which all reach a good standard of interest.

NOTES ON BOOKS

The second edition of *Cremation in Great Britain*,[b] prepared by the Cremation Society, is an authoritative and comprehensive account of the subject in its historical, legal, and technical aspects. The contents include the full text of the regulations for carrying out cremation, a detailed and illustrated description of each of the twenty-two British crematoriums, and architectural and engineering sections, with plans, diagrams, and articles, to aid local authorities and town-planning bodies. Special attention is paid to the changes in method and technique that have been recorded since the first edition of the volume was published in 1909. Of much interest to the medical profession is a carefully compiled bibliography, which starts with Sir Thomas Browne's *Hydriotaphia* (1658) and concludes with Miss Fidler's book on cremation, reviewed in these columns last year.

Miss BARBARA LOW has translated into English four lectures by ANNA FREUD, comprising an *Introduction to Psycho-Analysis for Teachers*.[c] These lectures were delivered in Vienna, to teachers primarily concerned with children between the ages of 6 and 14, and they deal from the Freudian standpoint with infantile amnesia and the Oedipus complex, the infantile instinct life, the latency period, and the relation between psycho-analysis and pedagogy. The work of translation has been well done, and the book, which is usefully indexed, comprises a simple but practical exposition of the outlines of the psychological development of children.

The *Unorthodox Reminiscences*[d] of Sir GEORGE TURNER, consulting surgeon to St. George's Hospital, are a mine of good stories about men in various walks of life, contain much about sport and racing, and, indeed, fully correspond with his dictum that "it is too absurd to think that a surgeon has no time except for his profession." He entered the Medical School of St. George's Hospital in 1873, at a time when for students "the tall silk hat was *de rigueur*, and woe betide any student who came up to the Corner' in a bowler. The offending hat was used as a football. He prescribes punching a ball and riding a home trainer, he has been in many accidents, having done "everything that was possible in this line in hansom cabs." The last chapter, on his service as temporary surgeon rear admiral in the war, shows that he had many interesting experiences, and confesses that he was sometimes "more than outspoken." In the preface he perhaps flatters himself by saying that he is "endowed with the gentle art of making enemies," but his reminiscences will certainly attract many readers.

Reference has been made more than once in the pages of the *Journal* to the work of Sir J. C. Bose on plant-physiology. He has now published a small volume[e] of the Transactions of the Bose Research Institute of Calcutta, placing on record the results of recent researches by himself and his scholars dealing with the problems of the ascent of sap, rhythmic pulsation, and the transmission of impulses under varying conditions. There has long prevailed a consensus of opinion that the rise of sap in plants is a purely physical process depending on root-pressure, supplemented by backwardly transmitted suction caused by transpiration from the leaves. Sir J. C. Bose's experiments seem to prove conclusively that there is a mechanism of sap propulsion independent of both of these physical factors, and that the ascent of sap is as truly a physiological process as the propulsion of the blood in animal physiology. Thus he has shown that the ascent of sap may occur in a stem which has been detached from the root, and also when transpiration has been eliminated by coating the leaves with vaseline. The direction taken by the sap is determined by the situation of the point of maximum cell-activity in the portion of stem experimented on, propulsion being in the direction away from this point. It is possible, therefore, to reverse the direction of the sap if the application of the stimulus is changed from the bottom to the top of the stem. The precise mechanism by which propulsion is effected has been demonstrated in the author's previous work. It is due to a peristaltic wave of cell-activity progressing along the whole length of the stem from the point of stimulation, and, being dependent on protoplasmic changes, it can be arrested by the application of protoplasmic poisons and depressants. Sir J. C. Bose's simple but beautiful and extremely delicate experiments on plants are well known, and many additional applications of them are described in the present interesting volume.

In his essay on the Causes of the Pforzheim Typhoid Epidemic of 1919,[f] which forms the tenth instalment of the Pettenkofer memorial volume, Dr FRIEDRICH WOLTER, director of the Hamburg Research Institute for Epidemiology, comes to the conclusion that this epidemic, the greatest which had hitherto occurred in Germany, cannot be explained by infection through water, milk, food, or contact according to Koch's doctrine, but can only be accounted for by Pettenkofer's theory of periodic climatic factors acting on a contaminated soil.

PREPARATIONS AND APPLIANCES

GLUCOSE D

Glucose D, issued by the Glaxo Laboratories, 56, Osnaburgh Street, London, N.W., is a high grade powdered glucose (98 per cent.) to which is added ostelin vitamin D and an easily assimilable calcium phosphorus compound. The makers claim that each ounce of the product contains the vitamin D equivalent of more than a pint of milk and the calcium equivalent of about half a pint of milk. One of the difficulties in invalid feeding is that an otherwise suitable diet may be very deficient in vitamins. The vitamin D and calcium added to this dextrose are not intended to provide medicinal doses of these substances but merely to help to replace any reduction in daily intake that may be occasioned by special dietary modifications, such, for instance, as the low fat diet necessary in acidosis.

THE STATE OF THE PUBLIC HEALTH

SIR GEORGE NEWMAN'S REPORT

[Second Notice]*

The year 1930 presented nothing of unusual interest for the epidemiologist. Even in respect of influenza it was one of the "between years," for while the severe outbreak of 1929 was followed by a milder outbreak in the early part of 1931, the intermediate year registered fewer deaths (5,019) from this cause than any year since 1911. During the first quarter of the present year the deaths numbered 9,384. Recent recrudescences of influenza have had their maximum in the age group 55–75, whereas in the epidemic of 1918 it was the younger age groups which accounted for by far the larger mortality. Wales was the most seriously affected area in 1931, and the least seriously affected in 1929.

Common Infections

Small-pox (variola minor), which continues to be of a mild character, showed an increased prevalence during 1930 in London and in one or two parts of the provinces. The total number of small-pox cases was 11,839, with 28 deaths. During the first half of the present year 4,570 cases were notified, with 8 deaths. Sir George Newman states that an examination of the behaviour of the disease during the ten years in which the minor type has been prevalent suggests that the number of cases in an area where vaccination and revaccination are not readily accepted, and where, therefore, it has succeeded in establishing itself, tends to increase to a maximum in the fourth and fifth year of incidence, after which it declines. If the present downward trend of incidence is maintained there is hope that the country may be relieved during the coming winter of the incubus of weekly infections which have ruled during the last decade.

Notifications of enteric fever (including paratyphoid) were slightly higher than in 1929—2,952 cases as compared with 2,835. Many practitioners, it is stated, fail to take advantage of the facilities gratuitously provided by the local sanitary authorities for bacteriological aid in diagnosis. A rise of 10,000 in the number of cases of diphtheria was not accompanied by a corresponding rise in the number of deaths, so that it is reasonable to hope that the large increase is due in part to greater care in the notification of mild cases. The type of disease has varied in severity in different outbreaks, but there is nothing to indicate that it has failed to respond to antitoxin given early and in sufficient dosage. Scarlet fever showed a noticeable fall in the number of notifications, with a very slight rise in deaths. Deaths from measles were slightly higher than before, and reference is made to the increased frequency of nervous complications in this infection. A few cases of undulant fever originating in this country have been reported, four of them concurrently in a South Coast town, where the probable source of infection was milk. The outbreak of psittacosis died away in the spring of 1930, after the prohibition of importation of parrots, but in October a group of three cases was reported from North Wales.† So far as is known, only one case of indigenous malaria occurred in England. The number of cases of dysentery notified was 538, and 97 cases proved fatal. The decline in the notifications of encephalitis lethargica, which has gone on uninterruptedly since 1924, continues, as does the decline in poliomyelitis and polio-encephalitis, but the number of cases of cerebro-spinal fever has gradually increased each year since 1923, and a similar increase has been recorded in other countries. Among epidemics in schools attention is drawn to an outbreak of epidemic catarrhal jaundice in a boarding school of 400 boys in a West Country town—the first such epidemic on a large scale in a public school.

The Growing Incidence of Cancer

The number of deaths recorded as being due to cancer again shows an increase. The total in 1930 was 57,882, as against 56,896 for the previous year. It is equivalent to a death rate of 1,454 per million persons living. The number has steadily increased year after year. In 1926 the rate was 1,362; the average for the five years before that was 1,269. The tendency to regard the annual increase of mortality as evidence of a growing inability to control the disease may be natural, but it is pessimistic. If it be true that a fraction of the increase is a natural consequence of the higher average age at death, and that another fraction is the result of greater diagnostic ability to recognize the disease, especially in the organs more deeply seated, it is clear, says Sir George Newman, that in the absence of some striking improvement in the methods of treatment, an annual increase of recorded mortality should not be received with surprise or dismay, and (bearing also in mind the long interval elapsing before the preceding pathological condition develops malignancy) may actually be expected for some years to come. Some observations from Scotland are cited which suggest that approximately three-quarters of the recorded increase in recent years can be ascribed to ageing of the population, and the remainder of the increase, with the exception of breast cancer, to better recognition of the disease.

Of the 26,284 deaths of males from cancer in 1929, 6,116 were from cancer of the stomach, 3,413 from cancer of the intestines, with a further 2,770 from cancer of the rectum. The site of next greatest frequency was the prostate, with 1,430 deaths. Of the 30,612 deaths of females, cancer of the uterus, of the ovary and Fallopian tube, and of the vagina and vulva, accounted for 6,022; of the breast, 5,944; of the stomach, 5,190; and of the intestines, 4,394. Cancer of the breast shows a real tendency to increase, cancer of the uterus a slight tendency to decline. There is no evidence, says Sir George Newman, of the association of genital cancer with multiparity; the real distinction is between women who have borne no children and women who have borne one or more. Clinically it has long been accepted that cancer of the cervix uteri tends to appear in lesions arising in the organ during childbirth, and the fall in mortality is reflected in the incidence, which in its turn is associated with improved care of the pregnant and parturient woman. The main problem of the causation of cancer is evidently not one and indivisible; there is a separate problem for each organ affected.

Tuberculosis and other Diseases

The figures relating to tuberculosis as a whole in 1930 were the lowest ever recorded in this country. The number of persons dying from all forms of tuberculosis was 35,745, as compared with 37,990 in 1929, and 36,623 in 1928. The deaths from pulmonary tuberculosis were 863 per million of the population among males, and 623 among females. All ages and both sexes share in the general decline. It is estimated that tubercle bacilli of human origin are responsibile for 50 per cent. of the deaths from tuberculosis in early childhood. Attention is drawn in the report to three interesting developments of after-care work now in progress: the residential provision for ex-patients at Fazakerley Sanatorium, Liverpool; the Sheffield scheme for the rehousing of tuberculous patients and their families; and the Burrow Hill Sanatorium Colony, for the treatment and technical training of youths. An alteration in the clinical type of pulmonary tuberculosis during the last twenty years is

* The first notice of the Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1930 appeared in the *Journal* of September 26th (p. 581).

† *British Medical Journal*, 1930, i, 887.

noted. There is a tendency for the disease to proceed less rapidly to a fatal conclusion, persisting with little toxaemia and few constitutional symptoms. The need for examination of the larynx in all cases suspected of pulmonary tuberculosis is the subject of a special note.

Venereal diseases are now treated at 190 centres, which last year dealt with 69,445 cases, together with 31,104 cases which were other than venereal. The number of cases for the first time dealt with showed a slight increase on the previous year, both in men and in women. Mention is again made of the low proportion of women with gonorrhoea dealt with at the centres. While the ratio of males to females in syphilis is about 1.8 to 1, that of males to females in gonorrhoea is 3.9 to 1, indicating that gonorrhoea is ignored by females even more than is syphilis. It is evident that, in the absence of a specific remedy for gonorrhoea, analogous to the arsenobenzene treatment for syphilis, the most hopeful line of attack on the incidence of gonorrhoea is much more intensive propaganda among women, with the object of inducing them to resort more freely to skilled treatment, and a great increase in facilities for intermediate treatment. There is a general impression that medical officers are still under-treating syphilis.

Under the heading of "rheumatism" Sir George Newman discusses the prevention of the acute condition in childhood as one of the new ideals of the public health service.

Food and Poison

An interesting section of the report is devoted to nutrition. Sir George Newman is of opinion that the nutrition of the people, notwithstanding the improvements of recent years, leaves much to be desired. There is still much apathy and ignorance in the choice of foods, often associated with deplorable cooking. "It is not too much to say that our national capacity for work and output is impaired by unsatisfactory nutrition." There is a widening sphere for investigation into the relation between nutrition and capacity for work, and between defects of nutrition and disease. It will be recalled that the Minister of Health recently appointed a committee, under the chairmanship of Professor Major Greenwood, to advise on the practical application of modern advances in the knowledge of nutrition.

A good deal is said in the report about milk. In the absence of any practicable means of completely eradicating tuberculosis from the herds, proper pasteurization, the report declares, affords a solution of the difficulty, and supplies a means of rendering safe the ordinary milk supply. As to whether pasteurization affects the nutritive value of milk, any alteration which could be produced by pasteurization could not be otherwise than small, and for ordinary purposes of nutrition negligible, when offset against the immense advantage of safety which pasteurization ensures.

An account is given of poisoning outbreaks, and of the cases of adulteration and contamination of food which have occupied the attention of the officers of the Ministry during the year. There were twenty-five outbreaks of food poisoning in 1930, which were responsible for 292 cases of illness and 16 deaths. The majority of these outbreaks were confined to families, or even to individuals, suggesting that food infection is at least as likely to occur in the domestic kitchen or larder as in the wholesale or retail shop or restaurant. Only one outbreak had an extensive incidence. This was due to contaminated meat pies prepared in a wholesale factory.

Administration of Public Health

The working of the Local Government Act, 1929, is the subject of extended reference. In speaking of the replacement of part-time medical officers of health by whole-time officers, Sir George Newman says that it must inevitably be some time before whole-time appointments can generally be secured throughout the country. Out of 1,200 medical officers of health in the country, only 375 are whole-time. But Section 58 of the Act means the ultimate passing of the part-time officer. Hitherto whole-time appointments have been mainly in the counties, county boroughs, and larger centres of the urban population; in the future, smaller urban and rural districts will come within this category. Hence the necessity of securing that the development of the services in the new conditions shall be such as will attract suitable candidates to a professional career.

It is also stated that progress has been made in the much-desired co-ordination both of public health services within the area and of hospitals—municipal and voluntary. Sir George Newman stresses the need for the fullest consultation between the local authority and the medical profession in regard to the usage of all the hospitals of the area in the public interest and for the benefit of the sick.

"Both types of hospital are desired and required, both will remain with us; what is needed is that they shall both be organized and administered together, to the maximum utility and advantage."

Finally, he returns to the national health insurance service—the front line of preventive, ameliorative, and curative medicine. As a scheme of organized general medical practice he admits that it is neither perfect nor complete. The war and its social aftermath gave it little chance. But as compared with the earlier club and contract practice—which is the long-distance comparison to make—there has been great gain. The large majority of the practitioners of England and Wales have elected to serve the community in sharing in this form of organized medical practice; the arrangements effectually bring the doctor and patient together on favourable terms, and the patient is receiving more, better, and earlier treatment than he did formerly.

"It is perhaps hardly too much to say that the principle of insurance has been introduced to our national life with a speed, zeal, and width of social application which is almost overwhelming Let us give it more time. Year by year the five partners in national health insurance—the insured person, the employer, the doctor, the approved society, and the Exchequer—are learning where the shoe pinches, where economy is necessary, and where extension practicable."

Insurance practice is the outpost of the attack against disease. By co-operating actively with his colleagues in the public health service in ensuring early notification, prompt isolation of infectious cases, disinfection, special treatment for cardiac conditions, cancer, tuberculosis, venereal disease, by his advocacy and practice of antenatal supervision, by his general advice on health and well-being, in a score of different ways the insurance practitioner is constructively and educatively applying medical benefit to the prevention of disease, alike by removing or lessening its primary cause, and by preventing and reducing its sequels. He is, in fact, "an integral part of a national organization of preventive medicine"

The Board of Education has published a booklet, entitled *Secondary School Buildings*, which contains suggestions for the planning of new buildings of this kind, and replaces the last issue of regulations, which appeared in 1914. The conclusions are based on discussions between the officers of the board and the officers and architects of local education authorities and Government bodies. The new publication deals in detail with such topics as the sizes and sites of schools, general planning and accommodation, ventilation, heating, and artificial lighting, water supply; and the arrangements advisable in institutions with boarders. The treatment of all these subjects is essentially practical. The booklet may be obtained from H.M. Stationery Office, price 1s. 6d.

British Medical Journal

SATURDAY, OCTOBER 10th, 1931

COMMON INJURIES OF THE KNEE-JOINT

The paper on the diagnosis and treatment of common injuries of the knee-joint, with which Mr. Naughton Dunn opened the session of the Orthopaedic Section at the Annual Meeting at Eastbourne, presents in succinct form a good survey of the subject, with an authority which only wide experience and careful observation can confer. In his introductory sentences he remarks on the difficulties of accurate diagnosis, and assigns these difficulties to their probable cause. Although the knee-joint is subcutaneous in three-fourths of its circumference, and might therefore be supposed to be easy of examination, yet many of the important structures that take part in its mechanism are beyond the inspection of the surgeon's eye or the palpation of his fingers. Of the twelve bursae that are described as connected with or in relation with the joint, only four are directly exposed to examination. Even when explored by incision, only a small part of the joint structures can be seen at a time, and it is not possible, without unjustifiable interference, to get a complete view of the whole. In such circumstances it is not surprising that out of the 522 consecutive cases with which Mr. Dunn dealt no fewer than 147 had to be classified as "indefinite" lesions. Sir Robert Jones and other speakers in the debate which followed the paper stated that in this respect their experience was similar. A large number of these cases of pain and limitation of movement following injury were no doubt due to adhesions; others, as Mr. Dunn suggests, were cases of subacute infective arthritis. Even when these cases were eliminated there remained a residue to which no cause could be assigned.

Much has been heard about the triumphs of manipulative surgery—as it has been called, to distinguish it from the surgery of the knife—though, as a matter of fact, all surgery is manipulative in the larger sense of the word. The kind of manipulative surgery which attracts so much public notice often has its greatest successes in the hands of those who have not chosen to lay the foundations of their skill by the study of anatomy, physiology, and pathology. Defined as Mr. Dunn defines it, as "ensuring the normal range of movement in a joint in any position," manipulative surgery may be of great value, and fully deserves his recommendation. As a means of cure of a displaced and locking knee cartilage, it has no permanent value. In this connexion Mr. Dunn's remark is of interest—namely, that 90 per cent. of the professional football players on whom he has operated had at some previous time been treated by bone-setters. No doubt a number of these were at the time claimed as triumphant successes for unqualified practice. Familiarity has dulled the edge of our wonder that structures of such apparent anatomical importance as the knee-joint menisci should be so easily dispensed with—structures, too, which have none of the characteristics of developmental relics. So many years have passed, during which so many knee cartilages have been removed, that there has been plenty of time for the production of end-results. It would be interesting to know the conditions twenty years after removal of a cartilage in a large number of knee-joints. Are such joints more liable or less liable to arthritis than their fellows, whether one or both menisci have been removed? Professional football players are admittedly prone to internal derangement of the knee-joint. It is, however, instructive to note that of the sixty-five players whose cases are included in these statistics, only one-half suffered from dislocated cartilage, thus roughly agreeing with the proportionate occurrence of such injuries among the total cases—namely, 250 in 522.

The diagnosis in these cases is classified under twenty-one headings, so diverse are the ways in which the knee-joint may be injured; but when the lesions of menisci, of the lateral ligaments, and loose bodies and indefinite lesions are excluded, only sixty cases of different kinds remain. Among these sixty cases, however, are many of importance and interest, illustrating the variety of conditions which it may fall to the lot of an orthopaedic surgeon to treat. In one respect Mr. Dunn's experience differs from that of most authorities—namely, in the relative frequency in his cases of lesions of the internal and of the external cartilages. All observers are agreed that the internal is more often affected than the external, but most authorities put the ratio between them at 1 to 7, whereas his figures were 1 to 2½. Whatever may be the explanation of this discrepancy, his figures are more than borne out by his operation statistics in professional football players, which show that in eighteen cases the external cartilage was operated on, and the internal in twenty-six, giving a still more striking approximation to equality of numbers for the two cartilages.

The subject could not be dealt with in all its aspects in the time allotted to it, and therefore the speaker confined his remarks to the operative treatment of knee lesions, saying practically nothing of the use of splints, radiation, or of heat or cold, and giving only a paragraph to manipulation. Among the lessons to be learnt from this paper is that thoroughness in operations on the knee is all-important, and that there is no certainty as to the condition of a meniscus until it has been exposed and examined, nor when one has been removed is it safe to assume that its fellow is in normal condition. Lesions of the lateral ligaments are usually serious injuries, not only on account of the damage to the ligamentous band itself—though that is not to be treated lightly—but also because of the extensive damage which may at the same time have occurred to the adjacent parts. Complete rupture of the external lateral ligament generally calls for suture,

but many surgeons will agree with Mr. Dunn that suture of the anterior crucial ligament is seldom likely to prove effective permanently. The history given of two cases of probable strain of the internal lateral ligament and suspected cartilage displacement, which were treated conservatively, is instructive. Both these patients, it is remarked, were able afterwards to play first-class football.

WHAT IS LIFE?

Dr. John Haldane of Oxford occupies a unique place in the medical world: he is a philosopher as well as a physiologist; he has made abiding contributions of the highest importance to our knowledge of the living animal body. When he expounds to us, as he does in his latest book,[1] which is an extension of the Donnellan Lectures, given in the University of Dublin last year, the conception he has formed of the ultimate nature of life, we are bound to listen to him with the most respectful attention. Nay, most of us will desire to agree with him rather than to differ from him. Of one thing he is certain: the ultimate problems of life, the essential nature of living matter, can never be solved in terms of physics, chemistry, or mechanics. As a man of science he admits that his own discoveries, and all the great advances made by physiologists in recent times, have been made just because he and they have applied to the study of life the precise methods of the physical, chemical, and mechanical laboratories. As a philosopher he maintains that these methods, although they will continue to throw light on living processes, will never explain the mystery which underlies them. "Never" is a dangerous word, even in the mouths of philosophers. How often has the apparently impossible been attained by men with even an imperfect conception of time and space and matter.

We are grateful to Professor Haldane for laying before us a clear description of the picture which rises in his mind when he is confronted with matter in a living state. It is very different, for instance, from that which rises in the mind of Sir Oliver Lodge. Sir Oliver believes that life is something which seizes and uses matter for its manifestations—an entity separable from matter. Professor Haldane adopts, what seems to us a more reasonable interpretation of appearances, the belief that life is inseparable from matter, that life is matter existing in a superphysical state. This superphysical state of matter (protoplasm, for example) is made manifest by certain powers—the power to reproduce, to build up structures, to maintain them, to repair them, and to co-ordinate all transformations of energy in order that some particular purpose or end may be accomplished. Matter in its ordinary physical states is devoid of such properties. Although Professor Haldane refuses to believe that the methods of physical and chemical research will ever explain the secrets of living matter—matter in a superphysical state—he cherishes a lively hope that some day there may come into being a knowledge of superphysics, and that biologists, with this new system of knowledge at their disposal, will swallow up the descendants of Einstein. At the present time physiologists go to the chemist and physicist for methods and inspiration. A glance at present progress in our knowledge of animal and human physiology makes it abundantly clear that every advance in the physical laboratory has its repercussion in the biological laboratory. If Professor Haldane's philosophy leads him rightly then a time will come when the physicist will go to the biologist to obtain enlightenment on the ultimate constitution of matter and for an understanding of what lies behind this mysterious universe of ours. To say, as Sir James Jeans has it, that our universe is a "thought" leaves us little wiser, for it is easier to form a mental picture of a universe than of a thought.

Living matter—if we have interpreted Professor Haldane's text aright, for on this aspect of his philosophy he is less explicit than he might be—can pass into a still higher or more specialized state than the one just described as superphysical. Living brain tissue, which manifests consciousness—has powers of memory, retrospection, and anticipation—is in a supra-superphysical state. For the interpretation of living matter in a state of consciousness Professor Haldane refuses to believe that chemist or physicist can give any light whatsoever. Biological methods of inquiry may help in the analysis of the phenomena of consciousness, but for the ultimate solution of the problem of sentient tissues there is no mode of approach—save philosophy. These are early days; science is still young; so is philosophy. If one might hazard a guess it would be to promise success to those humble beings who approach the problems of conscious living matter with earthly instruments rather than to those who seek to unveil them by a heaven-born philosophy.

As already indicated, *The Philosophical Basis of Biology* is based on the Donnellan Lectures. In these lectures we meet with our philosopher in a spirit of revolt—a revolt against the complacency which grew up in the minds of physiologists in the latter part of the nineteenth century, when they felt confident that all the processes of life would ultimately be interpreted in terms of physics and chemistry. The success which attended the efforts of those who approached the problems of life under this belief led them to minimize the extent of the field which remained untouched and unsolved. Professor Haldane's aim in these lectures is to compel physiologists to realize the extent of the field which lies outside the limits of their endeavours. His philosophy has led him, we think, to exaggerate the obstacles confronting the modern investigator. He has done well, therefore, to add to his lectures an appendix in which he reviews criticisms directed against his philosophy. He has met with a worthy champion of the modern methods of investigation in Professor L. Hogben, who, in his *Nature of Living Matter*, has extolled Professor Haldane as an investigator, but

[1] *The Philosophical Basis of Biology*. By J. S. Haldane, C.H., F.R.S., M.D. London: Hodder and Stoughton, Ltd. 1931. (7s. 6d. net.)

criticized him as a philosopher. We confess that in this matter our sympathies are with Hogben rather than with Haldane, and anyone who desires to know the criticisms which Professor Haldane would bring against the opinions we have expressed here will find them in that part of the appendix where he defends himself against Professor Hogben's attack. Whether we agree with Professor Haldane or differ from him on a particular issue our admiration remains the same for what he is and for what he has done.

MATERNAL MORTALITY

It is probable that the section of the annual reports of the Chief Medical Officer of the Ministry of Health which has attracted most widespread attention during the last few years has been that dealing with maternity. The public are becoming more and more familiar with the statistics of maternal mortality and puerperal sepsis, and it is not uncommonly held to be a reproach to obstetricians, general medical practitioners, midwives, maternity nurses, and public health medical officers, that in England and Wales these stand at over 4 and nearly 2 respectively per 1,000 live births registered, and that there has been no material alteration of these figures for a considerable number of years. In our abstract of Sir George Newman's report on "The State of the Public Health" for 1930 (September 26th, p. 581), the relative importance of this subject is fully emphasized, and an aspect of the matter to which we drew attention in an article on the corresponding report for 1929 (November 15th, 1930, p. 831) and which Sir George Newman now makes prominent in his new report, is referred to. It is this: that the relatively high incidence of maternal mortality in the whole country is largely due to the abnormally high incidence in two compact areas—Wales and the Northern Counties of England. If the rate of maternal mortality in these areas could be brought down even to the present average of the country as a whole, it is safe to say that that average would then be a cause of satisfaction rather than of reproach, though even then there would no doubt remain some particular authorities in whose areas the need for further effort would be apparent. Maternity has sometimes been described by those whose object has been to startle and alarm (no doubt with a good ultimate aim) as the most dangerous of dangerous occupations. This is not true of England generally, though it may not be wholly untrue of certain limited areas. It seems all the more necessary to insist that in these special areas more attention shall be paid to this matter, and more strenuous preventive efforts made. As Sir George Newman says with truth, "it is seldom fair to judge the maternal mortality of an area from the figures of any one year. The numbers are small in themselves, and an outbreak of sepsis or unexpected emergency cases may raise the rate temporarily. . . . But there are certain towns and districts which constantly have a maternal mortality rate considerably above the average for the country as a whole, and in any list of a dozen or twenty places where maternal mortality is highest the names of certain towns recur year after year." A list of eighteen such towns, in respect of the years 1923–29, appears in the report. They are all (with the exception of Plymouth) in Lancashire or the West Riding of Yorkshire, or on the very borders of those counties. It may be noted that of the two border towns Darlington (Durham) has jumped in 1930 from an average rate of 5.16 to the rate of 13.15, the highest in England; and Stockport (Cheshire) has fallen from an average rate of 5.3 to a rate of 1.7—amongst the lowest of those recorded last year. It would be interesting to have an explanation of this. The report suggests that in all, or almost all, these areas with a continuously higher mortality rate there is "apparent apathy" on the matter. We hope it will not long be possible for such a charge to be made with any justification.

POLIOMYELITIS

In a comprehensive review of the chief characteristics of poliomyelitis since the emergence of this infection from its endemic home in Norway and Sweden twenty years or so ago, and its subsequent spread over the world, including parts of the Tropics, Dr. Simon Flexner[1] of the New York Rockefeller Institute suggests that there has become discernible a natural process of immunization which may ultimately eradicate the disease. Northern America has latterly been suffering disproportionately, and Dr. Flexner attributes this to its population having been hitherto less exposed than the European nations to the infection, with a consequent lack of opportunity for the development of immunity. The infective organism in poliomyelitis is transmitted by the secretions of the nose and throat of carriers, as well as of infected cases. It is known that some persons harbour this organism for a time without any symptoms of disease, although a permanent immunity is gradually developed in them. Two small isolated outbreaks in New York State during the last few years were traced to milk, apparently a far more rare route of infection; they were characterized by their restricted extent and the rapid succession of the cases for a brief time, after which there was complete, or nearly complete, cessation. Subsequent immunity to this disease has been shown to depend on the presence in the blood of a substance which prevents the organism from causing the disease again. The serum of such a protected person, when injected into patients in the first stage, aborts the disease—the basis of the convalescent serum treatment of Professor Netter. The early investigations in the United States, by Anderson and Frost in 1911, led to later studies on a larger scale by the Harvard Poliomyelitis Commission under Dr. Aycock; these have indicated that such a preventive process seems to be proceeding steadily, and to promise a general eradication of the infection. Thus in childhood —when the disease reaches its highest incidence—little protection is discernible; from the age of 10 upwards the degree of protection rises, and susceptibility declines. The number of protected adults increases proportionately with increased exposure to the infection; it is, hence, higher in urban than in rural communities. In the present New York epidemic far more children under the age of 10 than over it have been affected. Protective serotherapy is still an uncertain procedure, but Dr. Flexner believes that benefit is to be expected. He

[1] *Science*, September 11th, 1931, p. 251.

adds that paralysis of the muscles is by no means an inevitable sequel, and may vary in its intensity. The extent of the paralysis at the beginning of the attack is no measure of its persistence; recovery from it often occurs.

MALIGNANT TUMOURS OF THE TONSIL

The operative treatment of malignant growths of the tonsil has always been one of the least encouraging fields of surgical enterprise. Unless the diagnosis is made at an early stage, when the growth is still confined to the tonsil, and an operation through the mouth still gives sufficient exposure, severe operations, including division of the mandible, as practised by Langenbeck, Bergmann, and Kocher, are necessary. Although the laryngeal drainage devised by Soerensen has made such operations less dangerous, they are nevertheless associated with a high mortality generally estimated to approach the neighbourhood of 30 per cent., and the ultimate results have been poor. Local recurrence and deposits in the lymphatic glands reduce the number of good results to less than 10 per cent. The introduction of diathermy for destruction of the primary tumour, combined with a radical dissection of the lymphatic glands in the neck, gave better results, so that in 1923 Norman Patterson was able to record seven cases of carcinoma of the tonsil which had been free from recurrence for periods up to eight years. A study by Elis G. E. Berven of the cases of malignant tumours of the tonsil[1] sent to the Radiumhemmet in Stockholm for radiological treatment reveals possibilities which compare favourably with the achievements of surgery. The report deals with a total of 86 cases; these include 42 cases of carcinoma, 4 of lympho-epithelioma, 35 of sarcoma, and five of malignant mixed tumours. A number of cases treated since 1927 have not been included in these statistics. Beyond this histological classification, each of these four types has been subdivided clinically into three groups, according to whether (1) the tumour is still confined to its original site and remains within its capsule, or (2) has produced palpable deposits in the regional glands which are still freely movable and would be operable, or (3) the tumour has begun to infiltrate locally and the corresponding glands have become fixed. In addition, the cases have been described in two sections because the original treatment by *x* rays externally with surface application of radium to the tumour has been replaced since 1924 to a great extent by teleradium treatment, rendered possible by an increased supply of radium. With the old technique twenty-eight cases of carcinoma were treated, and in seven of these the growth entirely disappeared, but in no case for longer than eighteen months. With the new technique of teleradium and surface application of radium to the tumour fourteen cases have been treated, of which four (three in Group I and one in Group II) have remained free from symptoms for more than three years. The group of lympho-epithelioma, not widely recognized in this country, and usually classified as sarcoma, but capable of recognition by a refined histological diagnosis, is important because of its high degree of radio-sensitivity. All the cases treated were free of symptoms for periods up to five years. Of the thirty-five cases of sarcoma fourteen were free from recurrence from four to fourteen years. There were six in Group I and eight in Group II. All in Group III succumbed. Of the five mixed tumours, corresponding mostly to the description of endothelioma, there are three from which the patients have had no recurrence for four, five, and six years. This statistical study brings out the possibilities of the recent methods of radiological treatment, but Dr. Berven refers also to a number of other conclusions in addition to giving a full clinical and pathological description of the tumours with their case histories and a complete account of the technique employed in the treatment. The results obtained do not indicate any possibility of obtaining improved results by combining radiological and surgical treatment, and the therapeutic object is to produce a slow, continuous disappearance of the tumour with the least possible reactive inflammation of its surroundings. Syphilis appears to exercise an unfavourable influence by weakening the reactionary capacity of the whole organism, so that there is an increased malignancy of tumours associated with this infection. The tumours grow rapidly and metastases occur early. Moreover, the changes in the vascular and connective tissues surrounding a tumour render them less resistant to irradiation than is normally the case. Treatment by teleradium avoids the violent primary reaction in mucous membrane caused by *x* rays, and as the ultimate results are better it shows a superiority over treatment by *x* rays, which is suspected in some cases of having caused numerous distant metastases. These are some of the conclusions reached by Dr. Berven, whose admirably illustrated book is full of carefully gathered details and demonstrates the importance of collecting both the radium and the clinical material in a large central institution, such as the Radiumhemmet in Stockholm. Decentralization has been avoided in Sweden, and the use of radium is limited to three centres.

NATIONAL INSTITUTE OF CHILD PSYCHOLOGY

It has been a common complaint of Continental and American visitors that there is no provision for the study of medical psychology in London. Especially is this true for those wishing to study child psychology. The medical profession in England has sometimes been criticized for its reluctance to accept new ideas; but in no profession, perhaps, is a conservative attitude more to be desired. Yet while this attitude secures a certain margin of safety it may at times, by its rigidity, impede progress. It is, however, now being gradually realized that the mind of the child, as well as the body, has its disorders—disorders which cannot be lightly dismissed by parental admonition and chastisement, but which demand the patient investigation and experiment so fruitful in their results in other departments of clinical medicine. The need for a separate machinery and personnel to provide adequate treatment for "the difficult child" has long been felt by physicians working in the out-patient departments of children's hospitals. To meet this need the Children's Clinic for the Treatment and Study of Nervous and Delicate Children was started three years ago. So successful has been its work, carried out in the face

of exceptional material difficulties, that it has now been possible to reorganize the children's clinic under the ambitious title of the National Institute of Child Psychology. What might be called the "clinical policy" of the institute is admirable in its conception. It has been wisely recognized that the "difficult child" must be investigated from the physical and the social aspect, as well as from the psychological, if any true solution of its problems is to be found. The child is studied as a living organic unit reacting to its environment. Play is an important method of self-expression for the child. In play its attitude to the world is unconsciously revealed. Its behaviour during play is therefore the starting point of the psychological investigation which is carried out by the medical director, Dr. Margaret Lowenfeld. The social background of the child is explored by a trained social worker. On admission to the clinic each patient is medically examined by Dr. Leonard Findlay, and a staff of specialists in the various branches of medicine and surgery act as consultants to the clinic. It was decided at a conference held in July of this year that the institute should be not only a therapeutic centre, but also a training centre for social workers, teachers, and doctors who need or wish for special knowledge of the emotional difficulties of children. A provisional syllabus has been drawn up for a training course of one year; there is a shorter course for medically qualified men and women. The importance of this work cannot be too strongly emphasized. That it should continue and increase is essential. For this, more money and accommodation are needed—a need which will, we feel sure, be satisfied when the institute's activities are more widely known in medical and lay circles. Anyone wishing for fuller information can obtain it from the medical director, Robert Browning's House, 19, Warwick Crescent, W.2, which is the institute's present headquarters.

THE CANCER CAMPAIGN IN AUSTRALIA

A brief reference was made in these columns on July 25th (p. 153) to the second Australian Cancer Conference, held at Canberra last March; the official report of this conference has now been received, and it is apparent that despite the prevalent financial difficulties real progress has been made in the promotion of research and in the education of the public. In a review by Dr. M. J. Holmes (of the Commonwealth Department of Health) of developments in cancer control in Australia during 1930, great importance is attached to the investigation of each case by a consultant committee, with a view to determining the most suitable lines of treatment. Such a committee, it is urged, should be brought into being in every treatment centre; it should be representative of all the clinical and pathological departments, and include a dental adviser; it should meet at least once a week to review all cases of cancer attending the centre, and the medical officer in charge of any patient should attend the meeting. Case records should be kept on lines as nearly uniform as possible, so as to facilitate statistical inquiries, and space should always be provided to indicate if the case is operable, borderline, inoperable, or very advanced, with the reasons for such classification. The conference agreed that a systematic follow-up of all patients should be more general than hitherto; without such a scheme it would be impossible to assess the results of the various lines of treatment, and progress in cancer therapeusis would be retarded. The card-index system, it was stated, had given good results in many institutions, regularity of the re-examination of patients being thus achieved. It was generally agreed at the conference that in many hospitals inadequate protection was provided against the dangers of exposure to radium, among the staff as well as the patients; each hospital was invited to determine the practical adequacy of the protective measures in force. In a statistical appendix to the report of the conference figures are set out which indicate that the increase in cancer mortality is mainly referable to the carcinoma group; the death rate curve for epithelioma, which was rising until 1918, appears now to have turned. In rodent ulcer the tendency is still upwards, but the sarcoma death rate remains fairly stationary. The August issue of the *Journal of the Cancer Research Committee of the University of Sydney* records that the cancer mortality rate is rising in each State, in both males and females, and this in spite of the fact that improved methods of treatment are resulting in a larger number of cures than was the case under the older methods. In this connexion Mr. F. L. Hoffman, consulting statistician to the Prudential Insurance Company of America, discusses in the same issue some principles of cancer statistical research, and indicates the importance of realizing that "cancer" is not an entity; each variety must be considered by itself if practically useful results are to be obtained.

TABULAE BIOLOGICAE

Tabulae Biologicae Periodicae[1] is a new scientific journal, edited by W. Junk. *Tabulae Biologicae* consisted of six large volumes of tabulated biological data, and it is proposed to continue publication in periodical form. This proposal has already been noted in the *Journal* (November 15th, 1930, p. 835), and we now welcome the appearance of the first two numbers of the new periodical. The scope of the volume is indicated by some of its chief contents, which are as follows: the chemical and physical properties of blood pigment and its derivatives (40 pages); the vitamin content of foodstuffs (18 pages); the chromosome numbers of plants (116 pages); the iodine content of vegetable foods (5 pages). These few examples indicate the wide range of subjects covered. The value of the periodical is best realized if one considers the time that would be needed to hunt up the information summarized in any table. The editor intends to publish quarterly numbers (one volume a year). The first volume will contain about 420 pages, and will cost 55 marks (48 marks to subscribers to previous volumes). This price seems quite reasonable in view of the fact that the work consists entirely of tabulated material. It is pleasant to welcome the appearance of a new periodical that will reduce, instead of increase, the labours of biological research workers.

[1] *Tabulae Biologicae Periodicae*. Herausgegeben von C. Oppenheimer und L. Pincussen. Band i, Nr. 1 und 2. Berlin: W. Junk. 1931. (Four parts, £2 15s.; subscription £2 8s.)

THE CAVENDISH BICENTENARY

Our knowledge that water is not an element, but a chemical combination of two gases, may be said to derive from the observation of Henry Cavendish that after an explosion of hydrogen with air (later he used pure oxygen), the "certain amount of liquid" present in the flask was "plain water." The long-drawn-out controversy as to whether Watt or Cavendish was the first to reach this conclusion is now ended. The former, in 1783, wrote that "water is composed of dephlogisticated and inflammable air," but without a knowledge of Cavendish's work obtained through Priestley (who had secured it in 1781 directly from Cavendish) it is improbable that Watt's conclusion would ever have been reached. Henry Cavendish, who was born at Nice on October 10th, 1731, and whose bicentenary occurs this week, is an example of the intellectual giant emerging occasionally from solitude with Promethean fire for men. Had there been no delay of nineteen years in publication, Cavendish, instead of Joseph Black, would be known to-day as the original theorist of latent and specific heat, and only a like delay makes Coulombe, instead of Cavendish, the discoverer of the inverse square law of electrical attraction. It is inevitable that the bicentenary of this very great man should be overshadowed by celebration of the birth of Michael Faraday. It should be remembered, however, that more than eighteen years before Faraday was born, Cavendish had observed the specific inductive capacities of glass, wax, resin, and shellac, and had determined their numerical ratios. Moreover, in the small portion of nitrogen which, he discovered, cannot be reduced to nitric acid, Cavendish had a sample of what Ramsay and Rayleigh in 1894 recognized as a new element, argon. His classical determination of the earth's specific gravity at 5.448 crowned Cavendish's later years. The rich, untidy, and eccentric recluse of Clapham was a giant of our race. He died early in 1810, having uttered, as Lord Brougham said, "fewer words in the course of his life than any man who had ever lived for four-score years." The Cavendish Physical Laboratory at Cambridge commemorates his name.

THE RISE OF PREVENTIVE MEDICINE

Sir George Newman, Chief Medical Officer of the Ministry of Health and of the Board of Education, is continuing the series of lectures under the Heath Clark bequest to the University of London, on "The rise of preventive medicine," at the London School of Hygiene and Tropical Medicine, Gower Street, on the following dates: October 13th, 15th, 16th, 20th, and 22nd. All the lectures commence at 5 o'clock, and are open to the public without ticket.

RECOGNITION OF DR. COX'S SERVICES

TESTIMONIAL FUND OPENED

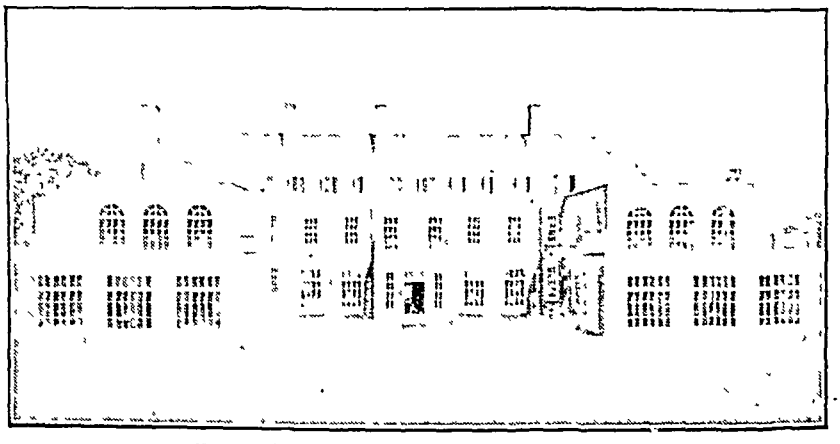
In the *Journal* of August 1st, 1931 (p. 199), and in the *Supplement* of the same date (pp. 105 and 116) reference was made to the steps that are being taken to recognize in a suitable manner the forthcoming retirement of Dr. Alfred Cox from the post of Medical Secretary of the British Medical Association. A representative general committee has been formed of members who, after inquiry, expressed their desire to be associated with the appeal, and from it an executive committee has been elected. A list of the members appears on the appeal forms, which are being circulated this month. The chairman of the general committee is Sir Humphry Rolleston, Bt., the chairman of the executive committee Sir Ewen Maclean, the honorary treasurer Mr. N. Bishop Harman, and the honorary secretary Dr. E. Rowland Fothergill, 6, Brunswick Place, Hove, Sussex. The appeal states:

"The Centenary Meeting of the British Medical Association in 1932 will coincide with the completion of Dr. Cox's term of service as Medical Secretary. Dr. Cox has held this position, including three years' duty as Deputy Medical Secretary, for the long period of twenty-five years, and during this time, as is universally agreed, he has accepted loyally the responsibilities of his important office, and has discharged its duties with unfailing devotion. His name has an assured place in the history of the Association from the date of the adoption of the new constitution to the celebration of the centenary year, and as he retires from office he carries with him the kindly thoughts and good wishes of innumerable friends, both at home and over-seas.

"The relations of the Medical Secretary are both official and personal. Thus on many occasions he has to speak for the Association in negotiations and conferences with various authorities and organizations, and here Dr. Cox has always stood firmly for the legitimate interests of the profession, and for policies which promote the welfare of the general community, while in more personal relations, and by his experienced judgement, courtesy, and goodwill, he has gained the regard and gratitude of the numerous members of the profession who have sought his counsel and help. In a word, Dr. Cox's professional and personal record is one of strong and sustained service rendered to medical interests and to public policy, and of loyal and whole-hearted co-operation with his colleagues.

"There is naturally a general desire among members of the profession to mark in no uncertain fashion their appreciation of Dr. Cox's large contribution to the success and prestige of the Association with which his name is so prominently associated; and not less appropriate is the proposal that some permanent memorial of the man and his work shall be secured for the Association's House and headquarters in London. To meet this end it has been decided that a portrait of Dr. Cox shall be painted by an artist of the first rank and presented to the Association in the course of the Centenary Meeting, and arrangements to secure this aim have been made. While, however, a portrait of Dr. Cox will be an interesting and valuable addition to the historical record of the Association, members will certainly wish to make some personal gift to Dr. Cox himself, and here the suggestion is that this should take the useful and flexible form of a substantial cheque, and of a volume carrying the names and addresses of all subscribers to the testimonial fund; a replica of the portrait for presentation to Dr. Cox may possibly be arranged.

"The full value and significance of such a presentation will be determined by the number of individual subscribers rather than by relatively large contributions from a limited number of members. Hence this appeal is for personal contributions not exceeding ten shillings in amount."



Contributions from members in the British Isles, Service members, and those outside any Branch area, may be forwarded direct to the Honorary Treasurer, Cox Testimonial Fund, B.M.A. House, Tavistock Square, London, W.C.1. In other parts of the British Empire plans are being made through the Branch and Division organization for issuing the appeal letter and for the collection of subscriptions. Canada and South Africa are making special arrangements through Dr. T. C. Routley (Toronto) and Dr. A. J. Orenstein (Johannesburg).

NEW SANATORIUM AT EPSOM COLLEGE

OPENING CEREMONY

Epsom College held high festivity on October 3rd, when its new sanatorium was opened by Lord Dawson of Penn, President of the Royal College of Physicians. A glorious day of St. Martin's summer showed the College buildings and grounds to their best advantage, while the new sanatorium, with its pleasant lines, its warm brickwork, and its mansard roof of red pantiles, appeared as a distinctive addition to the architecture of Epsom. It has provision for fifty beds, is completely separated from the other school buildings, and all its wards are arranged so as to have full sunshine and the benefit of the southerly breezes across the Downs.

About five hundred guests, including members of the College council, together with head masters, bursars, and medical officers of several public schools, assembled in a marquee adjacent to the new building. Supporting Lord and Lady Dawson on the platform were Sir George Newman, Sir Milsom Rees, Dr. Raymond Crawfurd (chairman of the College Council), Sir William Hale-White (treasurer), and Dr. Arnold Lyndon (chairman of the Sanatorium Committee). The head master (Mr. A. C. Powell) welcomed the guests, and described the new sanatorium as second to none and a model to all.

Epsom College Sanatorium. South Aspect.

Lord Dawson's Address

In the course of a brief address, Lord Dawson said that the completion of the sanatorium represented a further stage in the onward march of the school. During the last ten years well-planned developments had almost wrought a transformation in its buildings. The chapel had been rebuilt, a fine block erected for the teaching of chemistry, and a sports pavilion put up, and now the sanatorium was the latest manifestation of the far-sighted policy pursued by the council under the inspiring leadership of Dr Raymond Crawfurd. It was fitting that a school which had so many medical associations should set a high standard in its provision for health. After complimenting the architects (Messrs. Pite, Son and Fairweather) and others connected with the construction, including the medical officer (Dr. McBean Ross) and Dr. Arnold Lyndon, Lord Dawson emphasized the arrangement whereby the building can be brought into use in sections, each of which can be isolated as regards heating, lighting, and water supply. The provision for non-infective illness is quite isolated from that for infectious diseases; four infections —chicken-pox, mumps, measles, and influenza—can be simultaneously handled (graver infections being transferred, as hitherto, to fever hospitals), and the total beds available are sufficient to deal with those epidemics of influenza which occasionally visit public schools.

Lord Dawson went on to stress the value of physical education, which at Epsom was particularly well organized. Properly conceived, physical education (not the old mechanical soul-destroying drill), he said, was an effective means of training, on the one hand, mind and character in initiative, leadership, and power of expression, and, on the other, of training the body to beauty of form, resilience in movement, and that perfection of function of lungs and skin which gave endurance and adaptation to changing climate and resistance against disease. Physical education in too many schools "tumbled along," and some head masters had not yet begun to understand it. Instead of a few odd hours grudgingly conceded, physical culture should occupy a definite place, where it would enhance the value and enjoyment of games and sports.

The consideration of physical education led him to suggest that the duties of medical officers of schools should not be limited to the care of boys who are ill, but should include a study of physical education and its responsible co-operation in its purpose. This did not mean that medical officers should participate, still less interfere, in its day-to-day performance, but they should study physical education in being and its reaction on different boys. In this way the trained eye would detect in an early stage, and without formal examination, defects of frame and function when such could be easily rectified. The time to study a boy was when he was in movement. Defects of shape or expansion of chest, defective breathing, compensating asymmetry of frame, early flat foot, and cases which exercise produced fatigue rather than vigour, pallor rather than glow, could thus be detected, thus correlating the educational and the remedial. It was tragic to think how often medical men saw defects which could have been rectified in youth and which were a handicap to life's fulfilment.

In conclusion, Lord Dawson referred to the advantages of Epsom College in its proximity to London and in its surroundings and climate. It was upon its youth that England would depend for regaining the paths of civil prosperity and happy citizenship. "Equip youth well and let the full-grown man struggle for himself. To the child the community has obligations to help his growth into an effective citizen, but after that the debt of the man to the community is greater than that of the community to the man. . . . We have to train boys to hard and successful efforts to help themselves, and through themselves the country they love, and Epsom College is showing the way."

A Model School Sanatorium

At the conclusion of the address, the architect, builders, clerk of the works, and the medical officer and matron were presented. Lord Dawson was then handed a commemorative key, and proceeded to the door of the new building, which he unlocked, prayers of dedication being said by the chaplain. The company afterwards made an inspection of the building.

In addition to accommodation for the separate care of infectious and non-infectious cases, the building provides under one roof for out-patient attendance, observation and convalescence. It more than fulfils the requirements laid down in the *Memorandum on Public Schools Sanatoriums* recently issued by the Ministry of Health, and the standards there given with respect to floor space and

effective air space per bed are exceeded There are four eight bed wards, one four bed ward, and six single bed rooms Open air balconies are provided, as well as cheerful solariums fitted with 'vita" glass The administrative block at the front of the building includes an admirable room for x-ray work, a small theatre—with sterilizing room adjoining—for minor operations, a dispensary, a pathological laboratory, an inspection room, and offices for medical officer and for matron The sick accommodation is arranged on the ground and first floors, and the second floor is given over to the matron and staff Much ingenuity has been expended on details of installation, such as the maintenance of a constant temperature of 60° in all rooms, with 70° in the operating theatre, the provision in general of rubber floors, with quarry tile floors in bathrooms, sanitary annexes, and kitchens the rounding of all wall corners, and the use of doors of a special hospital pattern designed to prevent the accumulation of dust A number of the beds and one of the wards carry names of donors

THE TRAFFIC IN OPIUM

[From our Correspondent in Geneva]

One of the last acts of the Assembly of the League of Nations which ended last week was to receive a report by M Sawada of Japan, in the name of the committee which is charged with social activities, on the traffic in opium and other dangerous drugs M Sawada referred with satisfaction to the important advance represented by the establishment in 1931 of a convention for limiting the manufacture and regulating the distribution of narcotics He believed that the League was now in possession of an effective instrument for combating the evil One result of the new Convention, together with the previous Geneva Convention of 1925, would be to make the headquarters of the League itself a sort of counting house for the world drug traffic He also pointed out that the Convention covered a far larger number of drugs than preceding conventions, it brought codeine under control, whereas for many years morphine converted into codeine had to some extent, escaped all supervision it prohibited the export, except on very strict conditions, of a substance which has in the past bulked very largely in the illicit traffic—namely, diacetylmorphine—and it contained stipulations relating to reserve stocks and surplus stocks which would be gradually brought into use for legitimate consumption by a corresponding reduction in output, or would be disposed of under the sole responsibility of the Government concerned Above all, through a system of estimates furnished by the Governments, the Convention he said enabled a world total of the quantities to be manufactured to be fixed, and set up a supervisory body to examine this estimate

The powers and responsibilities of the Permanent Central Opium Board have also been enlarged It will be the duty of the Board not only to collect statistics from the various countries but also to prepare a statement of these figures, so that it may be possible to discover or prevent over production or excessive imports or exports or the accumulation of stocks which might find their way into illicit use Thirty six signatures to the Convention have so far been received, and the delegates of several other Governments, including those of China Colombia Persia, and Rumania, stated during the Assembly that they hoped to be able to sign the Convention shortly The rapporteur, speaking for his committee took the view that this limitation of the manufacture of narcotic drugs was the first step towards a subsequent limitation of the production of raw materials and he asked the Assembly to pass a resolution (which it did) requesting the Advisory Committee and the competent sections of the Secretariat of the League to undertake as soon as possible, the collection of all material that might serve as a basis for discussion at a future conference on the limitation of the production of opium and the cultivation and harvesting of the coca leaf Delegates of certain countries producing the material stated that they had no objection to this preliminary inquiry, though they hoped that other countries would pay due regard to the economic aspect of the question as it affected themselves The Persian delegate particularly stressed the difficulties involved in limiting production in a country whose opium exports amount to 25 per cent of its foreign trade

The Geneva Convention, 1925, has now been ratified by forty seven States, as a result of the recent accessions of Lithuania Norway, Iraq, Cuba, and the Irish Free State This Convention now more than ever heads the list of League Conventions as regards the number of ratifications received, though an important group of Latin American countries have not yet ratified Various useful measures have been taken in several countries In Germany, at the Government's request, the drug factories have given up manufacturing benzylmorphine (peronine) although this drug is not covered either by the 1925 Convention or by the new German opium law In Colombia a decree has been issued placing the import and distribution of drugs for medical and scientific purposes under the control of the National Health Office, and the Parliament there is considering a new law for the severe punishment of clandestine trading The Rumanian Government is preparing a new Bill to convert the drug trade into a Government monopoly The Swiss delegate made a very interesting speech in the Assembly He said that excellent results had been obtained in his country from the application of the measures of control of the various recommendations of the Advisory Committee regarding post and customs The output of morphine in Switzerland he said, had fallen from 2 246 kg in 1928 to 1,576 in 1930, the output of heroin from 952 kg in 1928 to 4 in 1930, while the exports of morphine had fallen from 1,761 kg in 1928 to 615 in 1930 and exports of heroin from 1 119 kg in the former year to 83 in the latter

The importance of the new regulations issued by the Turkish Government in February of this year under which *drugs may only be exported against an import certificate* issued by the Government of the importing country was also brought before the Assembly and a tribute was paid to the spirit of co-operation shown by the Turkish Government which has closed the Ethin narcotic drugs factory at Eyoub (Istambul), this factory having been implicated in illicit transactions The decline in addiction reported in Egypt, and the improvement of the supervisory system in Persia, were also noted favourably It is hoped that this latter system will make it possible to suppress the illicit traffic which has sprung up during the last few years at Bushire, its chief destination being China The report of the Permanent Central Opium Board to the council of the League was couched in rather less optimistic terms It stated that in 1930 more than ten tons of pure narcotic drugs found their way into the illicit traffic—a truly appalling quantity of poison—and, although the world manufacture of morphine and cocaine was last year reduced, this fact is unfortunately offset by an increase in the production of heroin, the most powerful of all these poisons, and the one with which medicine and science could most easily dispense

---

The seventeenth annual report of the British Guiana Infant Welfare and Maternity League states that with a view to the prevention of malaria—a very serious factor in the infantile mortality rate in that colony—mosquito netting and curtains for children's cots are being sold at cost price or even given away in the various districts where the league is operating and that excellent results have been obtained A relief fund is at present at work in thirteen centres to supply milk to mothers and infants who are suffering from malnutrition it is hoped that additional distribution agencies will be organized but further financial assistance is required from village authorities for this purpose Monthly and fortnightly clinics are being held in many towns and villages by the respective Government health officers assisted by the league nurses

OPENING OF THE WINTER SESSION

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

PROFESSOR H. R. DEAN ON "SCIENCE AND MEDICINE"

The formal opening of the session at King's College Hospital Medical School, Denmark Hill, took place on October 1st; the occasion was of especial interest because the school is just completing the first hundred years of its existence. Mr. A. D. Power, vice-chairman of the committee of management of the hospital, presided over a large gathering of students and others, and Professor H. R. Dean, Master of Trinity Hall, Cambridge, delivered the inaugural address.

The Chairman, in opening the proceedings, paid a tribute to the dean, Mr. H. Willoughby Lyle, who is shortly retiring from the office which he has held for many years. The Dean, in presenting his report, cited as indicating the growth of the medical school the fact that, when the new King's College Hospital was opened in 1913, there were between 50 and 60 students, whereas to-day there were 303. The number of fellowships, degrees, and diplomas obtained during the past academic year was 123. It was satisfactory to note that, in spite of adverse economic conditions, £26,924 had been contributed towards the £40,000 required for the centenary building fund.

Professor H. R. Dean, having distributed the prizes, prefaced his address by congratulating those connected with the hospital and medical school on being able to look back on a hundred years of hard work, progress, and achievement, during which three great King's College Hospitals had been built, each planned, erected, and equipped with generous foresight for the furtherance of the three great indivisible objects for which medical science existed—namely, the advancement of medical science by research, the care of the sick, and the instruction of those who came to be taught. Having briefly traced the origin and history of medical science and recapitulated some of its developments and achievements, the speaker said that those present would agree with him that, from the dawn of knowledge to the present day, there had been a very close association between science and medicine. In fact, there could be few new discoveries which would not in the course of time, in some way or other, play a part in medical progress. To medicine other sciences owed their origin, and it was fitting that these daughter sciences should, in their turn, make contributions to medical advance. No investigation in the principles of chemistry, or any branch of biology, could be so aloof from material needs that it might not at times yield results which would revolutionize practice. Indeed, the study of disease was a common interest, which united all concerned, whether workers in ward or laboratory, and progress could best be made when men with different points of view and knowledge worked together.

If it was believed, as it surely must be, that nearly every branch of science had made, and would continue to make, contributions to the advancement of medicine, what could those who to-day enjoyed that great inheritance of science do to make full use of the discoveries of the past and of the new opportunities which the continuous advance of science put ready to hand? In these days, in which the sum of all the sciences was so vast that nobody might know more than a fragment, specialization had become inevitable, and the need for co-operation was very real and urgent. But close association between all branches of medical science could be achieved only by close co-operation of workers in various fields, co-operation which, though vital, was very hard to achieve. The problem of correlation confronted all who entered the medical profession. The student, in the long years of his apprenticeship, was confronted by a series of courses and classes in the various branches of the medical sciences. Teachers had to be specialists, and must devote all their time to their subject. Thus it happened that in some subjects medical students were taught by those who had no knowledge of medicine and, consequently, no first-hand knowledge of the problems which awaited their pupils in the later stages of their careers.

Moreover, Professor Dean continued, each field of knowledge in which every student must browse for a little while was separated from the next by a fence, or an examination. It was not without significance that chemistry, physics, botany, and zoology had come to be termed the preliminary sciences, a term which seemed to imply subjects which must be completed and might be forgotten before the study of medicine commenced. If, as the speaker supposed, present-day students were more regularly taught, and had better opportunities for practical work than their predecessors, he could not help wondering at times why it had been thought necessary to increase the hours of compulsory attendance, the number of compulsory lectures, and to enforce, with greater severity, the system by which signatures were required for every course prescribed. To be signed-up might soon become the student's main objective! Did the need for signature lie in the fact that students were expected to attend, not only more classes than they would without a signing-up system, but actually more classes than could be attended with profit during the average span of a student's life? One of the most serious changes that had taken place during the past few years had been the handing over of the basic medical sciences of chemistry, physics, and zoology to the public schools. While the teaching of those subjects in many schools was excellent, the change of place in which instruction was given would render it much more difficult to achieve the co-ordination and correlation of all the branches of medical science, so badly needed to-day and, in fact, overdue. In the speaker's opinion the time had come for those concerned to put their house in order and to co-ordinate, if they could, the various fragments of the medical curriculum. In the process of reconstruction the majority of subjects would need pruning, and some might have to go altogether, for students were overworked and over-examined. But cutting down or cutting out would not be sufficient. Things would not become very much better until it was possible to recapture the ideal of one great medical science, or at least of one great group of medical sciences, using different methods, but united and welded together by one common purpose. Those whose privilege it was to work in that, the third King's College Hospital, might not think much of the second King's College Hospital, but it was there that their predecessors witnessed the development of the greatest advance in surgery that the world had ever seen, for in that second hospital Lister had changed the practice of surgery, and the world had followed him. Those attached to the medical school in that new and third King's College Hospital were entering the second centenary of the medical school. In the first hundred years of its existence that school had made history, and had handed down a great tradition. In the hands of present-day students rested the future of the hospital and its medical school.

A vote of thanks was accorded to Professor Dean on the motion of Mr. J. B. Hunter, seconded by Dr. H. Audley Lucas.

MIDDLESEX HOSPITAL MEDICAL SCHOOL

PROFESSOR McINTOSH ON "THE INFINITE INVISIBLE IN MEDICINE"

The prize-giving ceremony in connexion with Middlesex Hospital Medical School took place at Queen's Hall on October 1st. Mr. S. A. COURTAULD presided, and an address was given by Professor JAMES McINTOSH, director of the Bland-Sutton Institute of Pathology.

Professor McIntosh confined his remarks to bacteriology, and after a brief historical sketch of early epidemics, gave some account of the work of Leeuwenhoek, the Dutch microscopist, who, through the art of the microscope, discovered bacteria in the seventeenth century. The most powerful of his microscopes was said to have magnified about three hundred times. A further 150 years were to elapse, however, before the germ theory of disease was to be fully established by the work of such men as Pasteur, Lister, and Koch. The orator spoke particularly of the more minute disease-producing bacteria. He said that bacteria had been classified into the microscopic and ultra-microscopic. The larger or visible bacteria caused such familiar diseases as tuberculosis, typhoid fever, diphtheria, lockjaw, plague, and dysentery, while the ultra-microscopic viruses, as they were usually termed, caused small-pox, infantile paralysis, typhus fever, rabies, encephalitis, herpes, dog distemper, and many other diseases of animals and plants.

The orator proceeded to give his audience some idea of the size of these organisms. The smallest particle which could be seen by the unaided eye measured rather less than one-tenth of a millimetre or one hundred microns. The larger disease-producing micro-organisms, such as those of typhoid and diphtheria, measured from one to seven microns in length and about one micron in width. Therefore the area embraced by the minutest speck to be seen by the unaided eye would cover about two thousand of these organisms, whilst the same area would cover some three million of the more minute invisible microbes or viruses. It was this minuteness which was so difficult to appreciate, for the size approximated to that of chemical molecules; and, in fact, these filter-passers were smaller than the largest of the molecules, as, for example, the molecule of haemoglobin, which was some thirty micromillimetres in diameter. It had been calculated that the smallest virus known at present had a diameter of about twenty micromillimetres. The general consensus of opinion was that these bodies were alive, and, if they were not actually bacteria, were closely allied with them. The viruses could not be directly seen by the ordinary microscope, although in fluid media their presence, if not their form, could be made apparent by the ultra-microscope. Cultivation on the artificial media employed to grow ordinary bacteria had been so far a failure in the case of these viruses. Some of them, however, like that of small-pox, could be grown under conditions which would allow of the multiplication of tissue cells, known as tissue culture. Under such conditions and with living cells present, multiplication of the virus could be obtained in an indefinite series. It had been suggested that the presence of living cells in the cultures was necessary because these viruses actually lived and multiplied inside the living cells. In no instance as yet had it been possible to show that these viruses had a definite metabolism comparable to ordinary bacteria. So far the only real test of their presence was their power of multiplying in the animal tissues and producing disease. The fact that these viruses could live only in close relationship with living cells of the animal body suggested that they were much more parasitic than ordinary bacteria; many appeared to live actually inside cells, while ordinary bacteria only exceptionally did this, living mainly on the juices of the tissues in the intercellular spaces.

After a reference to the bacteriophage, the supposed virus which lived on and attacked living bacteria, Professor McIntosh said that apparently many of the characteristic features of the diseases caused by these viruses were the result of the close relationship between the virus and the cells. Further, the tissue cells which were attacked frequently showed highly characteristic changes in protoplasm, with the development of structures known as inclusion bodies. These peculiar bodies could be demonstrated by staining, and were, in certain instances, colonies or aggregates of the virus. Thus there were Guarnieri bodies in small-pox, Negri bodies in rabies, polyhedral bodies in diseases of plants and insects, nuclear inclusions in herpes, and so forth. There were scientists who declared that these viruses were not alive, and that they were of the nature of a ferment or enzyme, but a ferment could not increase or multiply, and their only similarity was that both could act in small or minute quantities. Others attempted to explain the regenerative or growth effects of these viruses by supposing that they were ferments which regenerated in some way from the destroyed body cells or bacteria. They suggested that these viruses were produced from the protoplasm of the destroyed cell in much the same way as Charles Creighton suggested that visible bacteria were the result of the disease, and not the cause. But the facts elicited in support of this view were not convincing. In support of the contention that they were living agents, experimental work showed that the action or effect of physical agents—antiseptics, heat, drying, and radiation of these viruses—approached nearer to the effect on ordinary bacteria than to that on ferments. Again, the invasion of the tissues during an attack of a disease such as small-pox led to the appearance in the patient's blood of antibodies which were capable of destroying or neutralizing the virus, whereas no such bodies followed the injection of ferments. These viruses, said Professor McIntosh, were apparently living bodies capable of multiplying within the tissues, where they called forth specific antibodies, and even a complete immunity, yet so small were they that they contained only a few molecules of protein substance. It seemed probable that in these viruses, just as in the case of the atoms, electrons, and protons in the physical world, the limit of size in biology had been reached.

THE SCHOOL YEAR

In the absence of the dean (Dr. Izod Bennett) through illness, the dean's report was read by Mr. PEARCE GOULD. He said that for some years past there had been a drop in the number of maternity cases needing domiciliary attention. This fact, together with rival claims of pupil midwives upon the available cases, had made it difficult for medical schools in London to provide for their students adequate practical experience in midwifery. During the past session an arrangement had been completed with the Royal Northern Hospital whereby the midwifery cases of that hospital and the surrounding district were made available for the training of students from the Middlesex Hospital. As a result adequate practical experience in this most important branch of medicine was assured for all students of the school, even allowing for a considerable increase in the present number of students. An increasing recognition of the importance of using radium in the treatment of malignant disease in strict accordance with the exacting detail involved in the modern technique, and, moreover, of keeping in continuous touch with cases thus treated, had, during the past year, led the hospital and the school jointly to appoint a whole-time medical officer in charge of this

work. The authorities of both hospital and school had already ample proof of the value of this new development, not only in the more encouraging results obtained from the use of radium, but in particular from the reliable statistical evidence now accumulating upon which before long it was hoped some definite conclusions might be based as to the true place of radium and *x*-ray therapy in the treatment of cancer. Reference was made to the loss sustained by the school in the retirement from the active staff during the year of Sir Arnold Lawson, Mr. Comyns Berkeley, and Mr. Herbert Charles, all of whom had been appointed to the consulting staff of the hospital.

Sir John Bland-Sutton, in distributing the prizes, said that if there was one pleasure greater than receiving prizes it was distributing them, and that day this pleasure was enhanced, because it concerned Middlesex Hospital Medical School, which he might call his own school, because he belonged to it, body and soul. It was only in this respect that he agreed with the Pauline charge to the elders of Ephesus, that "It is more blessed to give than to receive." It was a healthy instinct to strive for prizes, not only in college, but in the sports ground. The council of the school had a double object in awarding scholarships and prizes. Primarily, such awards attracted students of ability. Scholarships were assets when resident posts were being sought. Some were of sufficient value to enable the scholar to visit hospitals abroad—a good thing for curbing the natural vanity of the young, who found, oddly enough, that their equals in skill and knowledge were to be discovered outside the walls of their own hospital, and, indeed, all over the world.

Dr. R. A. Young proposed a vote of thanks to Professor McIntosh, remarking that while the addresses of the great astronomers and physicists at the British Association that week had directed attention to the infinitely great, Professor McIntosh had illustrated the significance of the infinitely small.

The vote of thanks was seconded by Professor Sidney Russ, who said that the work of the pathologist was taking him more and more into regions where the things studied must always remain invisible. A further vote of thanks, with many expressions of affection and of delight at seeing him back after his world tour, was accorded to Sir John Bland-Sutton, on the motion of Mr. Sampson Handley, seconded by Dr. R. C. Davis.

OLD STUDENTS' DINNER

The annual dinner of past and present students of the Middlesex Hospital Medical School took place at the Savoy Hotel on October 1st. In proposing the toast of "The School," Dr. Herbert Charles, from the chair, said that the west wing of the hospital was now complete, and contained the most up-to-date wards and theatres in London. The board hoped to complete the east wing and cross-piece early in 1932, so that the nursing home for private patients could be finished. The new hospital would have 700 beds, an increase of 308. He described the wonders of the nurses' home, with its splendid common rooms, seventy-six bathrooms, tennis and badminton courts, and swimming bath, the opening of which had been celebrated by an excellent display of diving and swimming by the nurses themselves. But he added that the board still required £210,000 for the completion of its great improvement scheme. Dr. Charles also expressed his sense of the privilege of occupying the chair, and claimed that the appointment of an anaesthetist to that position was a gesture of appreciation of the services of anaesthesia to the hospital and school.

Colonel W. Alan Gillett, in replying to the toast, emphasized the vital importance of the teaching function, which distinguished the voluntary hospitals and made them indispensable. He urged each member of the gathering to go out and proclaim boldly the part which voluntary hospitals might play in a national health service. Mr. Eric Pearce Gould, the acting dean, who also replied, announced an entry of students which eclipsed all figures since the exceptional years just after the war. He also mentioned that private nurses were now available for cases of every kind on application to the lady superintendent. A further reply was made by Mr. A. J. B Goldsmith, the senior Broderip scholar, who performed the traditional duty of voicing the grievances and other sentiments of the students in a most amusing speech, well in the traditions of the Middlesex Hospital.

The toast of "The Guests," proposed by Dr. G. E Beaumont, was coupled with the name of Sir Walter Fletcher, who, the speaker said, as secretary of the Medical Research Council, determined the direction in which medical knowledge should advance. Sir Walter Fletcher, in responding, drew a cheering picture of the Middlesex Hospital, in these depressing times, not falling, like the pound, but rising up in a magnificent new building with a record entry of students. No other hospital, he said, had such a splendid record in the field of research, a field in which all workers were essentially voluntary. The gathering closed with a warm personal tribute paid by Mr. Victor Bonney to the chairman, who briefly replied.

ST. BARTHOLOMEW'S HOSPITAL

OLD STUDENTS' DINNER

As in previous years, the new session of St. Bartholomew's Hospital Medical College was opened by the old students' dinner, which was held on October 1st in the Great Hall of the hospital. The chairman this year was Sir Percival Hartley, physician and lecturer in medicine. He was supported by the treasurer, Lord Stanmore, and other members of the governing body; Sir John Rose Bradford; Sir Holburt Waring; Admiral Sir Hugh Watson; Surgeon Vice-Admiral R. St. G. Bond; Air Vice-Marshal J McIntyre; Lieut.-Colonel Samman, Master of the Society of Apothecaries; the Masters of the Grocers', Mercers', and Farriers' Companies; the Dean of St. Paul's; Sir George Collins, Sheriff of the City; the Rev. Dr. Scott Lidgett, Vice-Chancellor of the University; Mr. Forrest Cowell, Secretary of the Royal College of Surgeons; the Deans of St. Thomas's and Guy's Medical Schools; and Mr. Edward Matthews, Architect to the hospital.

Sir Percival Hartley reviewed the progress of the year in a humorous speech, delivered in his invariably graceful style. He remarked that the centenary of Abernethy indicated a milestone in the hospital's history, but as long ago as 1662 students were receiving medical and surgical instruction there, while a little later John Freke, sergeant-surgeon to Queen Anne, was in charge. With Abernethy, however, the modern school of medical instruction might be said to have begun. The chairman congratulated Mr. Girling Ball on the success of the first twelve months of his deanship, and, mentioning the regretted departure of Sir Holburt Waring, added that a ward in the new surgical block had been named after him. This block, which had been in use now for twelve months, was realizing the highest expectations. The chairman expressed the hope that some day, not too far remote, the residential college might be again brought into being. With a view to improving the practical side of the obstetrical teaching an attempt was being made to co-operate with the City of London Maternity Hospital. After congratulating St. Bartholomew's Hospital on various athletic successes, including the winning for the

third time of the Rugby football cup, the chairman proposed the toast of "The Medical School," which was warmly received.

Dr. GEOFFREY EVANS, who proposed the toast of "The Guests," remarked that three voluntary hospitals were represented that night; he hoped that this might be taken as a happy omen for further co-ordination, and might develop into a unified medical service which could co-operate with municipal and other medical services in London. DEAN INGE, replying, caused considerable amusement by suggesting that medical practitioners had a great advantage over the clergy in that they saw their patients individually, and did not have to pour water over very narrow-necked vessels assembled in rows. He referred gratefully to the work of St. Bartholomew's in the City, and expressed the hope that, in spite of the national financial stringency, the money necessary for its improvement would soon be collected. The toast of "The Chairman," proposed by Sir CHARLES GORDON-WATSON, was drunk with musical honours.

ST. MARY'S HOSPITAL MEDICAL SCHOOL

ANNUAL DINNER

St. Mary's Hospital Medical School held its annual dinner at the Trocadero Restaurant on October 2nd. In proposing the loyal toasts, Sir WILLIAM WILLCOX, the chairman, claimed the reverent allegiance of all present to His Majesty, whose courage was so valuable a support to the country in the present stress, and their gratitude to the Duchess of York, the charming president of the hospital.

Lieut.-Colonel H. E. VEREY proposed the toast of "The School," and summarized the history of the past year in the form of a balance sheet. On the credit side he placed the new buildings, the foundation stone of which had been laid at a successful gathering during the past summer, and which would, he hoped, be ready for occupation by August next. The endowment fund had received an accession of £12,000. The out-patient department had been reorganized, and it was hoped that much of the waste of time so general in such departments would now be abolished. Arrangements had been made with the Paddington Borough Council for the provision of a unit of forty maternity beds. On the debit side, the extension fund appeal limped haltingly along; £120,000 was still required for the first section of the projected nurses' home, which would accommodate 225 nurses, but work would be commenced when £100,000 had been raised. The whole expansion of the hospital depended on an increased nursing staff. The London County Council, in framing its policy under the Local Government Act, had not been particularly interested in the fate of the voluntary hospitals; it had rather pursued the plan of *divide et impera*, and the big teaching hospitals of London had hardly ever been known to agree. He felt that the future of the voluntary system depended completely on the medical profession.

In responding to the toast, Dr. C. M. WILSON, dean of the Medical School, struck a note of defiant optimism. He said that eleven years ago there had been often only two applicants for the two university scholarships, and hardly six for all the public school scholarships, whereas this year the combined number of applicants had been sixty-two, all of them picked men. The Government grants had risen in his own time from £1,900 to £11,000. He appealed to the board to provide him with a hospital of 500 beds, and said that he would guarantee to push the entry to the highest number obtained by any London school. With regard to sporting matters, he mentioned that the Rugby team had reached the final for the first time in its history, and the boxing team had been runners-up. At the conclusion of an enjoyable evening, Sir WILLIAM WILLCOX, in reply to the toast of his health, proposed by Sir JOHN BROADBENT, gave many entertaining reminiscences of his connexion with the hospital and school.

ST. THOMAS'S HOSPITAL

OLD STUDENTS' DINNER

The winter session at St. Thomas's Hospital opened once again without formal ceremony, but the annual old students' dinner was held on October 2nd at the May Fair Hotel, with Mr. J. HERBERT FISHER, F.R.C.S., consulting ophthalmic surgeon to the hospital, in the chair. Among those at the high table were the treasurer, Sir Arthur Stanley, Sir Charles Sherrington, Sir John Rose Bradford, Surgeon Vice-Admiral R. St. G. Bond, Sir George Roberts, Dr. H. G. Turney, Mr. W. Girling Ball, dean of St. Bartholomew's Hospital Medical College, Professor T. B. Johnston, dean of Guy's Hospital Medical School, Mr. C. H. Fagge, and Mr. George Harcourt, R.A., who painted the portrait of Sir Cuthbert Wallace which hung in this year's Royal Academy.

Proposing the toast of "Prosperity to St. Thomas's Hospital and Medical School," the chairman made sympathetic reference to Sir George Makins's bereavement, recalling that Lady Makins had been a Nightingale nurse at St. Thomas's, where she soon won recognition from Florence Nightingale. In his reply Sir ARTHUR STANLEY gave the cheering news that financial stringency did not yet exist in its worst form at St. Thomas's. The hospital was able to go on for the present in its usual way, and while every possible economy was being undertaken, it was hoped that no cuts would be called for. Professor LEONARD DUDGEON, dean of the Medical School, was able to report that the numbers and work of the students of to-day were most satisfactory, with a fine record of academic distinctions. He mentioned, however, that all the London schools were now suffering from "under production" on their maternity districts, which made it difficult to give adequate training in midwifery. Co-operation with the Lambeth Municipal Hospital was proving a great advantage to St. Thomas's students, and for this the superintendent, Dr. A. L. Baly, deserved their thanks. A great step forward in medical education had been taken by Bart's, Guy's, and St. Thomas's, which now combined to examine candidates for university scholarships. The toast of "The Guests" was proposed in a witty speech by Sir PERCY SARGENT, and Mr. GIRLING BALL responded.

SIR CUTHBERT WALLACE'S PORTRAIT

The chairman then presented to Sir Cuthbert Wallace, on behalf of the subscribers, the excellent portrait which had been on view in the ante-chamber, and in so doing paid a warm tribute of friendship and admiration. In acknowledging the gift, Sir CUTHBERT said: "The repeated kindness of my old school makes the task of an adequate reply very difficult. St. Thomas's has given me most of the things that make life worth while—it has given me friends. It has given me life friends of which, Sir, you are one, and to me it is intensely pleasing that you should be in the chair to-night. It has given me good friends among my teachers, among my colleagues, among those I have taught, in the nursing world, and on the lay side of the hospital, from workmen in the basement to two treasurers in the counting-house. St. Thomas's has given me and taught me my profession and thereby a means of livelihood, but it has shown

me at the same time that there is much more in medicine than the scientific healing of the sick. Lastly, in this last gift it has given me another favour. I suppose that most people have a longing that when they go they will not be entirely and at once forgotten. So I hope that some time in the future in this portrait I may again enter the walls of the hospital, take part in its daily life, and share in its trials and its triumphs."

The proceedings ended with the toast of "The Chairman," proposed in appreciative terms by Mr. T. A. M. Forde.

CHARING CROSS HOSPITAL

PRIZE DISTRIBUTION

At the opening of the winter session at Charing Cross Hospital Medical School on October 2nd, prizes and certificates awarded during the last session were presented by Sir George Newman, who afterwards delivered the inaugural address.

Sir George Newman, speaking on the importance of preventive medicine, said that the end-results of medicine had too often determined its teaching and practice. Anatomy had been learnt from the dead rather than from the living, and the practice of medicine from the final entities observed in the hospital bed. Disease was a process, and medicine must be applied at an earlier stage if the end-results were to be avoided. More attention must therefore be given to conservative or preventive medicine. In England, the speaker continued, diseases such as cholera, plague, and typhus, which had once been terrible pestilences, had been conquered. To-day they were the actual witnesses of the control obtained over small-pox and other diseases. The infant mortality rate had fallen from 150 per 1,000 births to 60 in one generation. These were not the victories of hospital treatment, but the results of preventive medicine. Sir George Newman proposed four ways in which the study of this important subject could be advanced. The fourth- or fifth-year student should be taught the outlines of hygiene and preventive medicine in a series of lectures by competent teachers. This was done more thoroughly in the provincial than in the London medical schools. Secondly, the student should attend at certain clinics for instruction and demonstration in preventive work. Thirdly—the best method of all—the preventive principle and a preventive trend should be introduced into the main subjects of the curriculum. In the fourth place, a suitable examination should be passed before qualification. In this country, he said, there was a lack of appreciation by newly qualified doctors of the preventive trend of modern medicine. The public would soon be demanding preventive advice from the private practitioner, the real outpost of preventive medicine. In England and Wales 15,000 practitioners had already accepted service under the National Insurance Act, an Act passed by Parliament for the prevention as well as for the cure of disease. Was the public receiving an effective preventive service or not? If not, was it because the doctor was not trained to provide it, and perhaps did not appreciate that it was his function to seek the causes of the diseases for which he was consulted and then to control them?

Annual Dinner

The annual dinner of past and present students was held on October 3rd at Gatti's Restaurant, with Dr. J. M. H. MacLeod in the chair. After proposing the toast of "The Hospital and Medical School," he entertained his audience, in a delightfully informal speech, with personal reminiscences of his early life in London. In spite of prevailing financial difficulties Charing Cross Hospital, he said, was solvent. He paid a warm tribute to the work of the voluntary hospitals, a system which should not be interfered with. Mr. Eric Crook, the dean, replying to the toast, said that in response to their various efforts the medical school was growing, and made a reference to the success which had attended the recently instituted post-graduate courses. They welcomed, he said, the presence with them that evening of Professor Blair of King's College. The health of the chairman was proposed in a gracious speech by Dr. S. Cochrane Shanks, who indulged in a eulogy of Scottish heather and Scottish clans. Dr. S. Taylor Harris sang several songs, which were greatly appreciated, and the company adjourned to a dance held in the medical school.

MEDICAL DEFENCE UNION

The annual general meeting of the Medical Defence Union was held at Bedford Square, London, on September 24th, with Dr. W. S. A. Griffith, acting president, in the chair. Feeling reference was made to the great losses sustained by the Union in the recent deaths of its president, Sir Herbert Waterhouse, its treasurer, Dr. Seymour Taylor, and two members of its council for many years, Dr. Hedley Hill and Dr. W. Tracy Lydall.

Progress of the Union

Dr. Griffith went on to congratulate the members on the steady growth and prosperity of the Union. When he vacated the office of president, thirty years ago, the membership was 4,605, and the accumulated funds stood at £918. The membership now was 16,587, and the accumulated funds stood at £55,780. He said that the Union was consulted by its members on an increasing variety of subjects, and in any difficulty with which a practising doctor was confronted he was likely to derive great benefit from the experience which the Union had acquired. Two important stipulations were made before the assistance of the Union could be given—namely, that the subscription of the member applying must not be in arrear, and that the matter brought forward must concern a professional principle. It was to be regretted that there were still many practitioners who allowed themselves to remain unprotected against the attacks of unscrupulous persons, or the results of their own errors. He also drew attention to the friendly relations existing between the Medical Defence Union and the sister society, the London and Counties Medical Protection Society, relations which were furthered by a joint committee, whose business it was to explore misunderstandings and remove difficulties.

Solicitors' Report

The report of the council, which was adopted [illegible] story, but s unanimously at the meeting, gave a numb[illegible] medical ar of the range and variety of the cases dea[illegible] the year. The solicitors to the Union (Mes[illegible]ter John Free, reported that 110 cases had been referred to charge. With 1930. More than half of these were in resp[illegible] of medical on account of alleged malpraxis. Very fe[illegible] The chairman arisen in which libel or slander was the issu[illegible] of the fir to and during the war cases turning on libel[illegible]tioning th were as numerous as actions raising questions [illegible] praxis. The majority of such cases were those, of course, in which action was taken on behalf of members by reason of unjustifiable attacks upon them or their professional good name. Probably the activity of the Medical Defence Union in the past has helped to bring about the diminution of libel and slander cases; persons have learned the danger of seeking to attack a medical man who has been wise enough to safeguard himself by membership of a protective organization. The solicitors mention one matter in connexion with cases of libel and slander, which, they say, has led to some misunderstanding and perhaps to a feeling of grievance among members

Members often ask the Union to take action for alleged slander, and state that there will be no difficulty in obtaining witnesses. But the Union has declined to institute or even threaten proceedings for slander unless written statements from witnesses have been obtained. Otherwise, it is found that as the day of evidence draws near the memories of these witnesses suffer considerably. As to the charges of alleged malpraxis, these are usually cases where members are met with such an allegation in response to an application for payment of their account. More often than not the allegation is mere bluff, and if the position is resolutely faced, and the patients learn that the practitioner is not prepared thus to be intimidated, but is ready and willing, with the support of the Union, to fight the matter out in court, they realize that their bluff has failed, and that it is better to pay at once rather than run the risk of having to pay costs in addition.

Some of the cases described in detail in the report have been recorded in these columns as they arose, notably the action against a surgeon on the allegation that seven years previously he had left a pair of forceps in the patient's abdomen after an operation. The patient had, in the meantime, undergone another operation in the South of France, and the case turned largely upon the evidence of French surgeons as to their method of checking instruments. In the end a verdict was returned in favour of the defendant, with costs (*British Medical Journal*, 1930, i, 620). The costs in this case—well over £1,000—proved irrecoverable, except for the small amount of £120. Although by the awards of the courts the Union was entitled during 1930 to recover many hundreds of pounds, all that was recovered, owing to the fact that the litigants in most cases were without means, was about one-fourth of the costs.

Dr. W. S. A. Griffith, Dr. V. A. Jaynes, and Dr. A. Lyndon, the retiring members of the council, were re-elected.

ROYAL MEDICAL BENEVOLENT FUND

The number of new applicants helped during the last three months of each year has usually averaged about thirty-three cases, this being in addition to the grants which have been renewed to old beneficiaries on the books of the Fund. This year only seven new applications can be considered between now and the end of December unless further support is given to the committee. New subscribers are urgently needed in order that the activities of the Fund may not be curtailed during the coming winter months.

All who can are urged to send a subscription to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, W.1.

At the last meeting of the committee thirty-four grants were voted, amounting to £577 10s. The following are particulars of two cases helped:

Widow, aged 35, of M.R.C.S., L.R.C.P. The husband qualified in 1930, and a fortnight before he was to sail to take up an appointment in a medical service abroad he was accidentally killed, at the age of 28. The young widow is left with two infant children, a girl of 2 and a boy of 7 months. A man so recently qualified and cut off at the outset of his career is in a poor position to make provision for his family, and his widow is left with £55 a year. Fund voted £26 in four instalments. Personal service and possible further help will be given.

Widow, aged 38, of M.B., who died in November, 1930, at the age of 47. She is left with two boys, aged 9 and 6, to educate. The applicant is suffering from encephalitis lethargica. She is quite incapable of earning a living or even attending to her household affairs, mainly because she has reached the stage of Parkinsonism. A medical man, in supporting the application, writes that the husband was one who literally gave his life in the service of others. He never failed to help those in need, and the poorest of the poor were always his greatest concern. His widow is left with 30s. a week. Fund voted £26 in four instalments. Other societies are being approached to co-operate in this case.

MOTOR CARS FOR 1932

THE OLYMPIA SHOW

[From our Motoring Correspondent]

Once again the time has come round when "all roads lead to Olympia" for the annual inspection of the new models of cars that manufacturers are producing for the 1932 season. The Show, which is the twenty-fifth organized by the Society of Motor Manufacturers and Traders, will open its doors at 10 a.m. on Thursday next, October 15th, and continue until Saturday, October 24th. Considering the world-wide industrial depression, this year's exhibition will be found well up to previous standards, embracing not only chassis, cars, and accessories, but also sections for the display of appliances for the servicing of motor vehicles, and one for motor boats. So far as the car and chassis section is concerned, the stress of competition, coupled with the business depression, has not been without its effect, for the number of firms showing these has declined from seventy-four last year to sixty-one. While the international character of the Show is maintained—examples of the motor products of seven countries being on view—it is noticeable that the tendency is for it to become more and more national in character, British car builders leading with twenty-six different makes, American and French motor manufacturers being, however, again strongly represented.

Growing Popularity of Medium-power Cars

The chief feature of the exhibition is unquestionably the increased number of makes of cars equipped with engines of from 7 to 10 h.p. The growing popularity of this type of vehicle may be ascribed to two main causes. In the first place, the industrial world-wide depression of the past two years, and the recent national financial crisis in this country, with its accompanying heavier taxation, is undoubtedly causing motor users to study ways and means of effecting economies. Secondly, the low first cost and the moderate running and maintenance charges, coupled with the very satisfactory results they are giving on the road, have attracted many buyers, and, with the wave of economy alluded to, the trend of demand in favour of the low-powered car may be expected to be more marked than ever during the coming twelve months.

With regard to the question of prices, in view of existing costs of labour and material, as well as higher taxation, many people thought that bottom had been touched. Despite this, however, some manufacturers have found it possible to announce slight reductions, and although in the majority of cases prices, generally speaking, are unaltered, when the new cars are closely examined it will be found that they represent much better value than ever before.

Although emphasis has been laid upon the great development in small cars up to 10 h.p., this must not be allowed to eclipse the attraction of vehicles of greater horse-power, and, remembering the requirements of a large section of the medical profession, it may be presumed that interest will largely centre in the numerous examples of six-cylinder vehicles of from 12 to 15 h.p. which, in "sunshine roof" form, are being offered at prices ranging from £199 to £265.

The Trend in Chassis Details

From the point of view of mechanical detail no very startling departures in chassis lay-out will be found. A year or two ago there were writers who were foretelling the early disappearance of engines with only four cylinders, but the improvements which have been effected in them, and the satisfactory results they are giving in practice,

taken in conjunction with the necessity for economy, would appear to have given them a new lease of life. As has already been indicated, there is even in the popular-priced range of cars quite a number of attractive vehicles with six-cylinder engines, while for the more luxurious and costly types of cars the number of cylinders runs up to sixteen, with six as a minimum. Engine details continue to be the subject of careful study, resulting in better carburation and lubrication, while additional makers have fallen into line with new radiator shapes which, if not adding to general efficiency, certainly add to the attractive appearance of cars. Another change in constructional practice is the location of the petrol tank at the rear of the chassis, instead of above and close to the engine.

As regards ignition, the once universal magneto has almost entirely been displaced by a coil and distributor, using the lighting and starter battery as the source of current. While there are still those who regret the passing of the reliable magneto, considerable improvement has undoubtedly been effected in battery ignition, and, given the necessary attention which accumulators continue to demand, there should be no need for anxiety as to the regular and reliable functioning of the modern form of ignition. Clutches show little if any change, but, notwithstanding the increased efficiency of modern engines, there is a growing tendency to provide gear-boxes with four instead of three speeds, and the majority of makers now claim to give a "silent third," as well as a quiet-running top direct drive. In general, change-speed gear control remains unaltered, either by a centrally located or right-hand lever. It is to be noted, however, that not only is the Armstrong-Siddeley Company fitting its pre-selective gear controlled by a small lever on the steering column to all its different models, but that the same system has been adopted in a new medium-power Lanchester car. A device which appears to be catching on in America—for it will be found in several cars from that country—but which has not so far met with approval or adoption in Great Britain, is a "free wheel" incorporated in the transmission.

Bodywork Tendencies

The wire wheel with the large boss type of hub, and cover-plate giving access to the concealed detachable bolts, has increased in favour, while tyres incline to a slight increase of cross section. The longevity of the modern pneumatic tyre is such that car users can nowadays practically leave them out of their calculations of cost and maintenance, because of the immunity from trouble and the long mileages that they now afford.

Although there are a few motorists, medical and non-medical, who still prefer the open type of car, the popularity of the saloon is more pronounced than ever. It is, however, satisfactory to find that more attention is being paid to interior ventilation, and that the practice of providing a sliding sunshine roof is become more general. Bodywork of fabric construction is fast giving way to that of all-metal. Two improvements which stand out in 1932 body work are the increased girth and space of many of the hitherto very small cars, and the greater immunity from the noises that were formerly associated with all-metal bodies. Safety glass for windscreens and windows is fast becoming universal practice, while collision bumpers or fenders have now passed into the standard equipment of most cars. Complete as are modern vehicles, however, a visit to the accessory section of the exhibition will reveal a host of fittings which, if not exactly necessary, will be found to add to the comfort and convenience of motor users. Finally, it may be mentioned that those medical men who, in their leisure hours, indulge in the pastime of motor-boating, will find much to interest them in the motor-boat section, in which examples of every form of craft, from large cruisers to small boats with outboard motors, will be on view.

It may be added that the exhibition will be open daily from October 15th to 24th, from 10 a.m. to 10 p.m., the charge for admission on the opening day being 5s., on the two Fridays and Saturdays 2s. 6d., and on other days 5s. up to 6 p.m., and 2s. 6d. after that hour.

Next week it is proposed to review the main features of the exhibition, and to deal briefly with some of the new cars, and in particular with those suitable for the use of medical men, of whom to-day it may be said that practically all are motorists.

C. J. W.

Ireland

Dublin Slums

The Dublin Corporation has decided to borrow £1,000,000 for building new houses in the slum area, as well as for reconstructing some of the better tenement houses. The council moved that the recommendation of the Housing and General Purposes Committee of August 18th be adopted; that the terms and conditions of the proposed issue of £1,000,000 Dublin Corporation 4½ per cent. redeemable stock, 1955–75, referred to in the letter from the Irish Banks' Standing Committee, be approved of; and that a committee consisting of Alderman James Hubbard Clark, Councillors Sean T. O'Kelly, T.D., and David Coyle, be appointed, with full power to settle all necessary details in connexion with the proposed issue.

Distribution of Sweepstakes Money among Dublin Hospitals

After the cost of prizes and general expenses had been deducted from the sweepstakes money, £895,179 remained for distribution among nineteen hospitals in Dublin. The following hospitals in Dublin have discharged heavy debts, and are, in addition, carrying out many necessary improvements in equipment and in structural alterations Sir Patrick Dun's Hospital, from the sweepstakes on the Manchester November Handicap, 1930, and on the Grand National and Derby, 1931, received £108,578 7s. 2d.; of this, £90,000 has been invested, and an out-patient department is being built at a cost of about £34,000. The hospital's debt of something like £12,000 has been paid off. As more money comes in further building will be undertaken. When the committee knows the exact figure that will stand to its credit on the close of the series of sweepstakes yet to come, it will be able definitely to decide on its programme of reconstruction. Jervis Street Hospital, which also participated in the three sweepstakes, received £94,611 0s. 9d. The first thing that the hospital did was to wipe off its debt of approximately £30,000. There are about fifty men now working in the hospital at repairs and painting. Sixty additional beds have been provided, and eight new wards—four large and four small—with all necessary equipment. The x-ray department, the ultra-violet ray department, and the laboratory have received similar attention, and the governors have undertaken to build a school for nurses and premises for maids in Mary Street. Having discharged its debt, the Mater Misericordiae Hospital is building new annexes, which will contain bathrooms and all the necessary sanitary fittings for each ward. They will accommodate 310 patients. The Meath Hospital received £77,090 12s. 7d. from the last two sweepstakes. This hospital, like others, has suffered the loss of its Government grant (which amounted to £688 a year) and

also the contribution from the Hospital Sunday Fund—approximately £300 It has, however, cleared off its debt since the sweepstakes came to its assistance, and has invested £60,000 , £7,000 was set aside for building a new dispensary St Ultan's Hospital benefited from the three sweepstakes to the extent of £35,209 8s. 3d. ; having discharged a debt of £1,400, it has undertaken several improvements A new wing for babies and further accommodation for nurses have been provided. A flat roof now exists where the infants may enjoy the sunshine, the hospital has been externally plastered, and the grounds have been made more attractive. The board has invested £10,000 There is an up-to-date out-patient department, which has also been greatly improved. St. Patrick's Infant Hospital, Mountjoy Square, received £19,272 13s 2d from the last two sweepstakes, and has made good use of the money. A large overdraft has been wiped out, and three new wards have been provided at the Temple Hill premises, Blackrock, which were acquired as an extension to the Mountjoy Square house, where the accommodation was found to be inadequate. Richmond Hospital received £77,090 12s. 7d. as the result of the last two sweepstakes, and has invested the money until such time as the board learns what is going to happen in regard to the Government grant of £5,000—reduced from £7,000—which has been withheld from the hospital. A sum of £19,927 11s. 2d. was received by the Children's Hospital, Temple Street, as a result of participating in two sweepstakes. Like the other hospitals, it paid its debt and made provision for the future. A very necessary addition that has been made to the hospital is a lift, and a fine new sunshine department has been finished and is ready for use at the back of the hospital premises

Grangegorman Mental Hospital

Dr. Donelan, resident medical superintendent, in his report to Grangegorman and Portrane Mental Hospital Committee at Portrane, referred to the letter from the Department of Local Government asking for information on the manner in which funds to be received from the sweepstakes were to be allocated The ideal to be aimed at, Dr Donelan stated, was the removal of the institution into the country and its rebuilding on modern lines at a cost of probably £500,000 or more Assuming that to be beyond the capacity of the funds, he suggested the following improvements in the existing institution. (1) an amusement hall at a cost of about £8,000 , (2) hydropathic and electropathic treatment departments at a cost of about £2,000 each , (3) extension of the "vita" glass pavilion at a cost of about £8,000 , (4) improved furnishings in the day rooms at about £10,000 ; (5) improvement of roads and paths at Grangegorman and Portrane, about £4,000 , (6) a setting-up on modern lines of the pathological and bacteriological laboratory recently built at a cost of £800 Dr Donelan's recommendations were referred to a subcommittee for examination.

Health of School Children

The Strabane and Castlederg regional education committee has had an unsatisfactory report concerning the health of school children in its district. The school medical officer up to June 30th had examined no fewer than 1,453 children, of whom over 1,000 were suffering from some form of illness—616 alone from bad teeth. The Education Committee has had two dentists employed for eighteen months, and has now decided that the dentists must in future send monthly reports of their work The committee is disturbed over this state of affairs, and realizes, of course, that things must improve quickly if their schools are to remain on a level with the other schools throughout the province. The Strabane District Hospital board of governors decided that operations for tonsils and adenoids could be performed on condition that the committee pays fifteen shillings towards the cost of every case, but the Ministry of Home Affairs stated that such an arrangement was unnecessary, as the hospital must regard the treatment of these patients as the ordinary work of the hospital This may have the desired effect of lowering the percentage of ill-health among the school children. It is, however, believed that the Ministry's reference applied only to children who are eligible for free treatment and hospital maintenance under the Medical Charities Acts.

County Louth Board of Health

By five votes to four the Louth Board of Health postponed for twelve months the proposal to appoint an assistant county medical officer of health to Dr Musgrave, who urged the appointment. Dr. Musgrave said the appointment would cost the ratepayers only £150 a year The amount of work made the appointment essential if the health schemes, now four years in existence, were to be properly carried out. The chairman said the splendid work which had been done hitherto had cost the board a good deal less than the schemes which were in force in 1927 Diphtheria, which had been epidemic in Dundalk for generations, had been almost wiped out by the immunization scheme. When the result of the division was announced, the chairman said he was sorry to say it, but he believed the members of the board had failed in their duty. For the matter of threepence on the average ratepayer of £20 valuation, they had turned down a scheme destined to be of great help to the poorest classes in the towns and county districts of the country

Scotland

Welfare of the Blind in Scotland

The sixth report of the Scottish Advisory Committee on the Welfare of the Blind, covering the period from December, 1929, to May 28th, 1931, has just been issued. This committee was first set up in 1918 to advise the Department of Health for Scotland on matters relating to the care and supervision of the blind in this country. The report points out that in regard to the provisions devolving upon local authorities under the Local Government (Scotland) Act, 1929, there has been no change in the policy of utilizing voluntary associations. The committee holds that so long as a high standard of efficiency is maintained in the services for the blind carried on by voluntary associations, no attempt should be made by municipalities to displace these, although certification of blindness and the provision of allowances to the necessitous blind might be better undertaken by local authorities. The report expresses satisfaction that practically every town and county council has declared that it would remove the blind from the administration of the Poor Law and provide assistance under the Blind Persons Act instead of under the Poor Law. The number of registered blind persons in Scotland had continued to increase, and the total of 8,897 at April 1st, 1930, was 379 more than in the previous year. Of new cases, numbering 1,062, registered in the course of the year, at least 50 per cent had become blind after 50 years of age The percentage of registered blind persons under 16 years of age, on the other hand, had continued to show a decrease, thus indicating the beneficial results of the maternity and child welfare schemes carried out by local authorities Of the total number of blind persons 69 8 per cent were classified as unemployable for various reasons The report also discusses the question of the institution of a craft school for the blind

Dunfermline Orthopaedic Clinic

The medical welfare committee of the Carnegie Dunfermline Trustees reported on September 24th that arrangements had been made to transfer apparatus belonging to the trustees in their orthopaedic clinic to the Dunfermline and West of Fife Hospital, where it would be used in future for the treatment of patients in this institution. At the same time it was announced that the committee proposed, after consultation with its chief medical officer, Dr. Mackenzie, and the local medical practitioners, to establish a centre for the investigation of juvenile rheumatism. This centre will be opened at the clinic of the Carnegie Dunfermline Trustees on January 1st, 1932, and will provide medical practitioners with opportunities for the study of this disease in collaboration with a specialist in children's diseases.

Homoeopathy in Glasgow

A new homoeopathic hospital in Great Western Road, Glasgow, was opened on October 1st by the Earl of Home. Mr. Walter Currie presided, and Lord Home, in declaring the hospital open, said that many people in Glasgow would watch its progress with interest. He added that all the doctors who practised this particular form of medical treatment were fully qualified members of the profession, and that homoeopathy was simply a method of administration of the ordinary drugs. Dr. F. B. Julian of Liverpool, who also addressed the meeting, maintained that the orthodox school of medicine was dominated by the idea of a specific for each disease, and that in homoeopathy there was a definite principle of treatment whose further investigation and application promised good results. The hospital has originated from a meeting held in the Merchants' Hall, Glasgow, in December, 1908, when it was resolved to form a public homoeopathic dispensary. This has been carried on since March, 1909, at 8, Berkeley Street, Glasgow, and last year the committee of management acquired a building in Great Western Road, which has been remodelled to provide numerous small wards, with an operating theatre and sterilizing room.

Edinburgh Blood Transfusion Service

A voluntary service of persons willing to offer their blood for transfusion in urgent cases has been established at Gilmore Place, Edinburgh. The service was inaugurated some nine months ago, and an appeal is now being made for increased membership. Donors are at the disposal of the medical profession in cases of pernicious anaemia or of loss of blood through accident. As a rule those who have supplied a pint of blood are not called upon for another transfusion until two months have elapsed. Advantage is being taken of the service, which has received as many as five calls in one week-end. Intending donors are requested to communicate with the organizing secretary.

Banff Hospital Reconstruction

At a meeting of the trustees of the Chalmers Hospital, Banff, held on September 16th, a scheme of reconstruction and improvement for this hospital was adopted. The scheme is estimated to cost approximately £10,000, and will increase the number of beds from 45 to 74. An intimation was received from the secretary of the local voluntary collecting committee that this committee would undertake to be responsible for collecting £3,000 towards the scheme if the work was started at an early date. The trustees decided, therefore, that part of the scheme, involving about half the contemplated expenditure, should be commenced immediately. This portion includes the installation of a new electric lighting system, a new building for plant, and new heating arrangements.

Dundee Royal Asylum

The 111th annual report of Dundee Royal Asylum states that the revenue for the year was £7,290 and the expenditure £7,307, while the capital fund at the disposal of the directors amounted to £61,501. According to the report of the medical officer, Dr. Arthur B. Dalgetty, there were 58 patients on the register on June 15th—one more than on this date in the previous year. Patients admitted during the year numbered 19, including 5 men and 14 women, of whom only 5 were certified. Eleven inmates, including 7 voluntary patients, were discharged, and 7 died. Of the deaths, one was that of a woman aged 102 years 10 months.

England and Wales

Lord Mayor Treloar Cripples' Hospital

The annual report of the Lord Mayor Treloar Cripples' Hospital and College for the year ending March 31st, 1931, mentions that not a single child has been refused admission to this institution, despite the work of rebuilding which has been going on. Details about these new extensions were given in the *Journal* of October 25th, 1930 (p. 707), but it may be added that the isolation hospital gained five cubicles of the most modern design during the year under review. This expansion has become necessary through the development of orthopaedic work at Alton; the more frequent admissions and discharges in that department have increased the possibility of infection, and, therefore, the necessity of taking more stringent precautions. The new Connaught ward was completed and opened in December, 1930, and the Portsmouth ward in June of this year. Besides these building operations the development of the college at Alton has been the subject of anxious consideration. The trades previously taught were the making and repairing of boots and shoes, tailoring, and leather work, including the production of suit-cases, portmanteaux, attaché-cases, and fancy leather goods. With the advent of mass production and mechanized forms of manufacture, it has become increasingly difficult to find suitable situations for crippled boys in factories. On the other hand, those trained in tailoring or bootmaking are better able to earn a living by working in their own homes, or in smaller establishments, and there is also a greater demand for training in boot and shoe making. The trustees have therefore decided to reorganize the college so as to provide greater facilities for giving instruction in the bootmaking shop, and to accommodate there a larger number of boys, while reducing the number to be trained in the leather shop. The latter shop will not be closed, however, but will deal with a smaller number of those who are most fitted for the work, and have greater prospects of obtaining employment in that trade. Sir Henry Gauvain, the medical superintendent, calls attention to the most important point that successful sun treatment does not require constant and intense sunlight; alternating shade and darkness in turn are as essential for the sun cure as is light. This form of heliotherapy is a shock treatment, and the changes from darkness to light have definite curative value, whereas continuous exposure to light has none. Sir Henry Gauvain maintains that sunlight treatment in England is of much greater benefit than it is in the Tropics. Similarly, in the case of sea-bathing for surgical tuberculosis, he finds that this shock treatment is particularly useful in raising the metabolic activity. It is a powerful accelerator of the healing process, and is of special help in cases of discharging wounds. He believes that there is some property in sea water, not found in fresh water,

which is of undoubted curative value; the benefits obtained by immersion in salt water do not occur when fresh water is used. Graduated sea-bathing associated with heliotherapy is the routine treatment for the majority of patients at Hayling Island, and excellent results are being obtained.

Chartered Society of Massage and Medical Gymnastics

The third annual dinner of the Chartered Society of Massage and Medical Gymnastics took place at the Connaught Rooms, London, on October 2nd, under the chairmanship of Mr. R. C. Elmslie, and a very large company of members and guests assembled. In proposing the toast of "The Society," Captain Ian Fraser referred to the kindly assistance it had given to blinded soldiers entering the profession, but added that in his judgement the society now exhibited too much zeal in the initiation of students. While agreeing in theory with the new rule that massage treatment should only be given under medical supervision, he considered restrictive rules not always good; the spirit of the law was the essential thing. Mr. Elmslie, in responding, replied to a criticism on the ground of overcrowding of the profession; out of a total membership of 8,000, he said, only 1,500 were in private practice. He announced that Lord Moynihan had accepted the presidency of the society in succession to Sir Cooper Perry. After referring to the auspices of the Society of Apothecaries' *Bio-Physical Assistants* recently set up under the new rules, and defended the ordinance that treatment should only be carried out under medical supervision. He also said that advertising was unethical, and no member who had the interests of the society at heart would stoop to it. Miss J. H. Wicksteed proposed the toast of "The Guests," and responses were made by Mrs. Ivens-Knowles and Dr. A. E. Barclay. The former congratulated the society on its wise organization to protect the public from unqualified practitioners, and welcomed the extension of physical therapy to obstetrics and gynaecology; the exercises now practised in hospitals would be of great benefit in puerperal cases. Dr. James Mennell proposed the toast of "The Chairman," speaking of his great work for the establishment of orthopaedic hospitals, and the toast having been drunk with musical honours, Mr. Elmslie briefly replied, thanking the staff of the society for their work, and especially for the organization of another successful congress. During the evening a telegram of loyal homage was sent to the Queen, who is patron of the society, and later a reply was received. A telegram of greeting was also sent to Sir Cooper Perry, whose services in obtaining the charter, said the chairman, would always be gratefully remembered.

Ethel Hedley Orthopaedic Hospital for Crippled Children, Windermere

The Ethel Hedley Orthopaedic Hospital, Calgarth Park, Windermere, is one of the institutions linked with the national scheme for the cure of cripples. Although the hospital was opened in 1920, this is its first report, covering the work of eleven years; it contains a good deal of information about the cases treated. There was a small epidemic of poliomyelitis in Lancashire, Westmorland, and Cumberland in 1910, which resulted in a number of deformities and disabilities for which no treatment was available. In 1911 and 1913 the North of England again suffered from small epidemics, and it was decided in 1920 that if another epidemic occurred every effort should be made to treat cases at once in order, as far as possible, to prevent the onset of deformity. Accordingly, when the disease reappeared two years later, the forces prepared beforehand were mobilized, with the gratifying result that, in the fifteen cases treated by special splinting, plaster frames, etc., not only were contractional deformities entirely prevented, but the power of the affected muscles was restored to a remarkable extent. The hospital contains fifty beds and a small recovery ward, and helps to serve eight after-care clinics. The medical director, Dr. C. H. Hough, states that all the beds have been continuously occupied. The average number of the staff is thirty-two, and the average weekly cost amounts to £2 17s. 8d. Thanks to the continued generosity of Mr. Hedley, the management is freed from all financial anxiety.

Correspondence

BENDIEN METHOD OF CANCER DIAGNOSIS

SIR,—The Investigation Committee of the British Empire Cancer Campaign has inquired into the Bendien method of diagnosis for cancer, and finds that, although the preliminary results were encouraging, subsequent inquiries have failed to justify the early promise. The Investigation Committee, therefore, has come to the conclusion that the Bendien method of diagnosis for malignant disease cannot at the present time be accepted as reliable.

—I am, etc.,

C. GORDON-WATSON,
Chairman, Investigation Committee.

London, S.W.1, Oct. 2nd.

RHEUMATOID ARTHRITIS

SIR,—The letter of "Crippled" in your issue of October 3rd (p. 630) is, I think, of more value to the interested than are many which are more dogmatic. The sex preponderance of rheumatoid arthritis is, I believe, very generally accepted, but timely reminders of such a fact are valuable when we have to face, as we have now, the problem of the local focus of infection and all it implies. When we collect evidence on the subject we are met with difficulties on every side. Some cases seem so obvious that for the moment all appears to be clear; the obvious focus is removed, improvement follows, or if there is delay many maintain that a careful use of a suitable vaccine will complete the recovery. Other cases are, however, most unconvincing, for there is no evidence of a local focus suggested in the history or found on physical examination. Even then we are left unsatisfied, because we know that we cannot exclude every possibility of local foci, which year by year are being discovered in unsuspected sites and which may apparently lie latent.

Again, there may be difficulties equally great when we have found and dealt with a local focus; for what may be the result? It may be this—that we see a patient with active rheumatoid arthritis, and later see the same patient edentulous and without tonsils and still with active rheumatoid arthritis. Once more it may be said that the treatment of these local foci had been undertaken too late. Worse disasters may happen, as illustrated by the recent interesting paper by Dr. L. Abrahamson (*Journal*, July 4th, p. 8), which I can support with comparable cases of patients who have exchanged for septic teeth and compensated heart disease, no septic teeth but malignant endocarditis.

The history of tonsillitis and acute rheumatism has close bearing on these problems, for it shows how highly sensitized the rheumatic child may become to streptococcal infections. The throat infection may be of the slightest, but the outburst of rheumatism severe. From the study of the morbid anatomy it is difficult to picture a rheumatoid arthritis arising without infection acting as the lighted match; possibly this infection is influenza possibly a "cold," possibly a local focus undiscovered

Nevertheless, we also cannot escape from such unexplained facts as the greater frequency in females of the acute rheumatism in childhood and of the rheumatoid arthritis in young adult life, the tendency of the daughters of gouty parentage to develop rheumatoid arthritis rather than gout, and the influence of nerve shock and strain.

We can understand a vaccine assisting in the cure of an obvious infection, but such a vaccine may not be able to cope with sex incidence, nerve strain, hereditary predisposition, or unsuitable surroundings added to this infection; and we can understand that a local focus stirred up to special activity may just turn the balance against a sensitized patient. The rheumatic diseases are so difficult to investigate and often so disappointing to treat that we need continual reminding that around them is concentrated the struggle over the problem of what the term "infection" implies.—I am, etc.,

London, W.1, Oct. 5th. F. JOHN POYNTON.

SIR,—In the *Journal* of October 3rd "Crippled" makes the entirely reasonable deduction that, as the sex incidence of rheumatoid arthritis is predominantly female, therefore neither dental nor tonsillar infection can be causal. I entirely agree with him (or should it be her?).

Not only so, but there is a very grave danger of aggravating the disease if the supposed foci of infection are interfered with. A most tragic case occurred in my own experience when a woman had some pain and weakness of the smaller joints of the hands and feet. Her tonsils were removed. Thereafter the advance of the disease was so rapid that from the day of the operation she remained in bed for six months. Rheumatoid arthritis is a general disease with marked toxic features, as opposed to osteo-arthritis, where the health is seldom impaired. Any operative treatment will lower the resistance still further, thus accounting for unhappy results.

At the Charterhouse Rheumatism Clinic it is the deliberate policy of the staff not to interfere with foci of infection in typical cases of rheumatoid arthritis occurring in young women, but to treat them entirely by stock vaccines. So far there has not been a failure to cure early uncomplicated cases. When cure is complete, and only then, should any removable focus be dealt with, since foci of infection are, of course, a potential source of ill-health.

Our results at the clinic fully justify the dogmatic statement that, in treating rheumatoid arthritis, interference with supposed foci of infection is *not* a necessary preliminary to cure.—I am, etc.,

London, W 1, Oct 2nd. H. WARREN CROWE.

MENORRHAGIA OF OBSCURE ORIGIN

SIR,—I was very much interested in Dr. James Young's article "Menorrhagias not due to uterine disease" in the *Journal* of September 26th; and after having read it, what occurred to me was the fact that, in a large percentage of cases, the primary cause was unknown, or, to use his own word, obscure. Therefore the treatment he adopted in those cases was purely symptomatic.

This subject has aroused much interest on the Continent, and especially at the Peham Klinik in Vienna. Hofbauer, who for some time has proved experimentally that the Schroeder syndrome can be produced by feeding guinea-pigs on anterior pituitary lobe extract, recommended *x*-ray therapy to the pituitary body in such cases in women, and under his directions the Peham Klinik has had very encouraging results. Hofbauer himself told me that hitherto his work was founded purely on an experimental basis, but recently he has had the good fortune to examine the pituitary body in women suffering from menorrhagia who had died of some other condition. One case was that of a woman suffering from menorrhagia who died as a result of a street accident. In those cases he found that the anterior lobe of the pituitary body showed definite signs of over-activity. I look upon Hofbauer's work as a distinct step forward in the elucidation of what Dr. Young describes as an "obscure" condition.—I am, etc.,

Hull, Sept. 28th. A. PATRICK, M.B., F.R.C.S.Ed.

SPINAL ANALGESIA

SIR,—In the *Journal* of October 3rd Dr. Falkner Hill states that novocain "has absolutely no paralytic effect on the vasomotor centre whatever. The proof of this will appear in a paper now being prepared for publication, in which it is shown that the injection of novocain into the cisterna magna has no such effect. If the direct application of novocain to the centre itself has no paralysing effect on it, it is idle to suppose that any dose absorbed from the lumbar theca into the blood stream could affect it in this way." But a subarachnoid injection of novocain into the cisterna magna is no more a direct application to the vital centres than is a lumbar administration. This is a fallacy of direct medullary action all over again, and any conclusions based on such an assumption will be likely to have as little clinical value as those of Koster.

Nevertheless it will be interesting to have the results of his cisternal administrations. His test tube experiment with durocaine describes the slow descent of the mixture into the subjacent cerebro-spinal fluid owing to the gradual evaporation of the alcohol, and exactly corresponds with what I predicted in my paper in relation to spinocain.—I am, etc.,

London, W.1, Oct. 3rd. W. HOWARD JONES.

CARDIOSPASM

SIR,—May I be permitted a few comments on Dr. H. B. Butler's interesting case (September 26th, p. 565). I prefer the older title (as above) to the humorous one coined by Sir Cooper Perry; the exact pathology of the disorder is still open to argument.

The type of case described by Dr. Butler (in which there is no actual spasm) is easily dealt with by dilatation by the air-bag method. I described this method fully in the *Journal* as long ago as October 11th, 1913. The passage of the bag, its inflation with air, and its subsequent slow withdrawal by gentle traction, should be done always under fluorescent screen observation; only thus can it be safely done; the air-filled bag is easily seen, and its slow passage through the cardia is readily followed.

This, however, is not the difficult type of case; for then one has to deal with a real persistent spasm of the cardiac orifice—a spasm very difficult to overcome, whether from above by a dilator or from below by open operation. This genuine cardiospasm goes on for years, and the oesophagus becomes enormously dilated, with its lower end expanded into a great horizontal sac; from a point toward the left side of this sac, the narrow passage into the stomach is directed vertically down. In such a case it is impossible to pass any kind of tube or dilator into the stomach unless guided by a thread, and even with a thread as guide it may prove impossible to pass a tube into the stomach. Even then an operation is not, in my opinion, either justified or likely to succeed; correct treatment, however, can and will do much to overcome the spasm and restore the patient to good health. All my genuine cases of cardiospasm go to prove that the complaint is due to a combination of (1) traction of a large heavy stomach on the cardia; (2) toxaemia of the tissues concerned, being part of a general toxaemia due to chronic

intestinal stasis and (3) an idiosyncrasy which I cannot explain My complete bismuth x ray examinations of the alimentary tract have confirmed this in every case of genuine cardiospasm With regard to the stomach, it is remarkable that this organ should be constantly enlarged and overloaded, although for years food has not been able to enter it except in small amounts at infrequent intervals, proof positive that there was gastric enlargement prior to the oesophageal trouble

The treatment briefly, is (1) to prevent traction on the cardia by an abdominal support and abdominal exercises, (2) to relieve spasm (cardiac, pyloric, ileo caecal, colonic) by moderate doses of belladonna and alkali and (3) to combat the toxaemia of stasis by diet, paraffin, kaylene, and colonic lavage Steady improvement follows this treatment even in the worst cases, and, though not so satisfying as the dramatic cures achieved when dilatation is possible the final result is even better, since the patient is relieved of toxaemia The improvement that follows dilatation is so great that the need for general treatment is apt to be forgotten, though highly necessary —

I am etc,

ALFRED C JORDAN, MD MRCP, DMRE

London W 1 Sept 26th

ETHER CONVULSIONS

SIR,—The riddle of ether convulsions is still unsolved They have been attributed in turn to impure ether, to excess of CO, to excess of oxygen and to its lack, and cases occur which appear to confound each theory Deep anaesthesia is the only common factor, but since convulsions are not frequent, and a flaccid patient is often demanded, another line of research must be sought

Convulsive manifestations may be produced by a shift in the *p*H of the blood, either to the alkaline side as in tetany, or in the acid direction as in uraemia, and one observer tells me of a case of ether convulsions which strongly resembled uraemia

It might be feasible for a sample of blood to be collected in a hypodermic syringe, when a case occurs as near as possible to the time of occurrence of the convulsion so that any change in *p*H could be detected The more suddenly such a change took place—due, perhaps, to uneven anaesthesia, especially further deepening—the more likely would it be to cause a cerebral disturbance, in the endeavour to cope with it (just as occurs in a sudden oxygen deficiency where a gradual change may be compensated)

The sample should also be tested for histamine, which has been suggested as a possible cause It seems well established that ether sensitizes to histamine, and the only case which I have had so far tends to support this theory as it occurred in a man aged 29, badly crushed in a pit accident His signs were those of a ruptured viscus but at the end of a complete investigation of his alimentary tract no perforation was found At that moment the convulsions started as described I gave O, and the surgeon was able to stitch up, but the patient died half an hour after returning to the ward There was extensive bruising of the omentum, and post mortem a rupture of the vena cava was discovered The patient was anaesthetized with a Shipway apparatus and a semi closed mask Respiration had been of a rather shallow type but there was no cyanosis until after the convulsions started

A passage in Professor Samson Wright's *Applied Physiology* reads "The increased excitability of the nervous system may be analogous to that found in tetany, and may be due to a disturbance of the balance between the different ions of the blood" If this be true of uraemia, why not also in ether convulsions? It is at least worth looking to see, and if results agree as to the presence of a blood change, it will be a hint for preventive treatment before operation, designed to increase the margin of safety although nothing should take the place of watchful care, during the operation, to avoid the other factor, the one which is already known—namely, tendency to overdose —I am, etc,

B E COOK

Doncaster Sept 29th

FATS IN THE CAUSATION OF PEPTIC ULCER

SIR —Your leading article in the *Journal* of August 15th, on hunger pains in pyloric and duodenal ulcer deals fully with the two theories which up to the present have held sway The cause of the hunger pain in one case is hyperacidity at the height of, or end of gastric digestion, the acid having an irritant effect on the producing mechanism or on the mucous lining of the stomach, causing spasm, and, by reflex action pain The other theory is that the pain is chiefly due to abnormal motility, the peristalsis increasing when the stomach is empty, or practically so The ingestion of suitable food induces the stomach contractions to quieten down as your article points out, the hunger pains may be a symptom of pyloric gastritis Dr Arthur F Hurst puts forward the theory that in persons who suffer from peptic ulceration there is an inborn hypersthenic diathesis, and a constitutional tendency to hyperchlorhydria

One would have liked consideration of another theory, explained at length in a book recently published (*The Causation of Chronic Gastro Duodenal Ulcers* by J Jacques Spira) Briefly, this work points to a food factor as responsible for the disease, and fat in excess the offending article of diet

The presence of fat in the stomach produces delay in evacuation of its contents stimulates concurrently the secretion of bile in the liver and hydrochloric acid in the stomach At the same time it causes duodenal regurgitation into the stomach with prolonged irritation of the pyloric mucous membrane and consequent pylorospasm and hypertonus from mixture of bile salts and acid gastric contents The pain is induced when this retro-peristalsis begins and ceases the moment some chyme passes through the pylorus—that is on resumption of normal peristalsis

This work also puts forward new ideas as regards the causation of chronic peptic ulcers and acute peptic ulcers, the etiology and pathology of each being different I consider that the theory set forth in this book should be developed, and the change of treatment as regards diet tested by other medical men The author has had excellent results over a period of several years The surgeons who perform gastro enterostomy and partial gastrectomy also claim excellent results, but surely operation in any but complicated cases, where there is structural deformity, is merely mutilation Then again, many patients suffering from gastro-duodenal ulceration, and from the pre ulcerative stages, do well on massive doses of alkalis and numerous feeds of milk eggs with olive oil, etc, which, according to this new theory are contraindicated Certainly no more depressing form of treatment than the above could well be devised but the complete rest in bed, which is invariably insisted on is of immense value and a big factor in relief from symptoms The period of rest following surgical treatment has similar good results

The new theory, of course indicates a line of treatment in which only a small quantity of fat—in the form of fresh butter for its valuable vitamin content—is allowed as also are small doses of alkalis Otherwise a non fatty dietary must be worked out and be strictly adhered to —I am etc

J M ANDERSON

Hove Sept 26th

*** Reference to Dr Spira's theory was made in a leading article in the *Journal* of September 12th, on "The role of fats in the stomach"

THE SYNDROMES OF THE JUGULAR FOSSA

Sir,—The case recorded by Dr. A. F. Tredgold in the *Journal* of September 26th is of particular interest to the otologist. Syndromes of the jugular foramen (that is, involvement of the ninth, tenth, eleventh, and sometimes the twelfth cranial nerves) are occasionally met with in association with diseases of the ear, so it happens that a primary ear case turns up as a case of hoarseness.

At the moment I have under observation a woman, aged 34, with hoarseness of some duration. The right vocal cord is paralysed, as are the right side of the soft palate, the right superior constrictor, the right sterno-mastoid, and the right trapezius muscle. There is no sensory loss in the palate or larynx. The tongue is not paralysed. The right ear is the subject of a chronic otitis media with a large perforation. Hearing is impaired but present. The *x*-ray of the mastoid is negative. There is a history of relapsing pleurisy. In view of this the diagnosis is tuberculosis of the temporal bone, involving by compression the nerves traversing the jugular fossa. The lesion is an extension of the ear condition, which is probably tuberculous. A case akin to this was recorded by Mr. Harold Kisch (*Proc. Royal Soc. Med.*, Section of Otology, February, 1931). In his case the lesion was tuberculous, confirmed by a microscopical examination of tissue removed at operation.

In light of these two cases it would be of great interest to know the post-mortem ear findings in Dr. Tredgold's case. Was there any evidence of tuberculosis? He does report that, clinically, a granulation, with perforation of the tympanic membrane, was present on the same side as the lesion in the temporal bone. The neurological syndrome in his case is that of Hughlings Jackson, who first described, in 1864, the homolateral paralysis of the larynx, soft palate, tongue, sterno-mastoid, and trapezius. Vernet (*Journ. of Laryngol.*, xxxiii, No. 12, 1918, p. 354) gives an excellent summary of the various syndromes of the jugular foramen.—I am, etc.,

London, W 1, Sept 28th. N. Asherson.

DIPHTHERIA CARRIERS

Sir,—In an article on diphtheria carriers in the *Journal* of September 26th Dr. James Grant refers to nasal carriers which "practically always had a sore or small excoriation of one or both nostrils, frequently with an acrid nasal discharge," and which "at first yielded practically pure cultures of Klebs-Loeffler bacilli." He also says that he had little doubt that nearly all these carriers harboured virulent bacilli, as they were intimate contacts of diphtheria cases. Surely these so-called carriers would be more correctly described as cases of nasal diphtheria, and as such should be notified and effectively isolated.

In the Medical Research Council's publication on diphtheria a carrier is defined as "a person who harbours in his throat or elsewhere virulent diphtheria bacilli without exhibiting manifest signs of the disease." Are not excoriated nostrils with an irritating discharge yielding positive cultures manifest signs of the disease? I am convinced from my own experience that if diphtheritic rhinitis were more frequently recognized and treated as such the incidence of faucial and laryngeal diphtheria would drop considerably. Too often, because of the generally slight constitutional disturbance, and the relatively infrequent formation of membrane, nasal diphtheria is missed, or, when recognized, regarded as merely a temporary carrier condition.

My opinion is that a missed case of nasal diphtheria is the primary focus of infection in many outbreaks of faucial diphtheria, and as the condition is commonly regarded as "only a sore nose," the child is allowed to attend school or mix freely with other children, passing infection to its susceptible contacts. The irritating nasal discharge induces picking of the nose, and the child's hands readily pass on the infection. In contrast, the true nasal contact carrier, having no nasal irritation or discharge, is relatively non-infective.—I am, etc.,

George Chesney, M.B., D.P.H.
Poole, Dorset, Sept. 29th. Assistant M.O.H.

DIABETIC ACUTE ABDOMEN

Sir,—I was interested to read the case of diabetic acute abdomen reported in the *Journal* of September 19th by Drs. Lawrence, Millman, and Pilkington. Some years ago I had the opportunity of seeing many of these cases when serving as house-physican to a distinguished physician, long since passed away. His constant method was to give, for a few days, a full ordinary dietary with unlimited carbohydrates; then to ascertain the percentage of sugar passed in the urine for twenty-four hours, and the presence or absence of acetone. Then he would suddenly change the dietary to a carbohydrate-free diet, with plentiful proteids and fats. The patient's condition generally changed rapidly for the worse, and within a few days there were complaints of abdominal pain, rapidly becoming an agony, with some vomiting, complete anorexia, great unrest, and anxiety. The objective signs were a generally tender and retracted abdomen, a reddish-blue facies and extremities, marked unrest, and much dyspnoea. However, a sign which was always most marked was the well-known strong, sweetish, stale, alcoholic smell which pervaded the breath and whole being of the patient. This odorous sign can never be forgotten by anyone who has ever smelt it, and in my humble opinion this should be a most useful guide to the diagnosis of this condition. I could not see any mention of this symptom in the interesting case detailed in the paper.—I am, etc.,

Beaumont H. Comerford, M.D., D.P.H.

London, S.W., Sept. 28th.

AN IMPROVED WHITEHEAD'S VARNISH

Sir,—A simplified and inexpensive modification of Whitehead's varnish has been in use at the Hospital for Sick Children, Great Ormond Street, for many years, and has proved invaluable as a dressing seal. The following record of its composition and preparation may be of interest.

Whitehead's varnish is composed of the following: gum benzoin, 4 parts; styrax, 3 parts; balsam tolu, 1 part; ether, 40 parts; with the addition of 10 per cent. iodoform. All five constituent drugs are antiseptic when used. The action of iodoform is well known, and its presence is not always necessary or desirable in a varnish.

Prepared styrax or storax contains an oily liquid and resin, cinnamic acid and its esters, and closely resembles balsam of Peru in its action. Balsam tolu contains benzoic and cinnamic acids and their esters, and resins. Benzoin (*B.P.*) contains cinnamic acid, free and combined, benzoic acid, and numerous aromatic substances. Ether is likewise antiseptic. The combination forms a mildly stimulating antiseptic application. It has the disadvantage of not drying readily, of being unduly expensive, and, furthermore, iodoform is frequently unnecessary.

The original sealing agent for wounds was no doubt the balsam traumaticum of the 1746 *London Pharmacopoeia*. This was replaced by compound tincture of benzoin, or friars' balsam. Both were popular, and almost universally used as domestic remedies. Collodion

then became an official preparation, and came into favour with practitioners. Collodions such as those of the *British Pharmacopoeia* and *British Pharmaceutical Codex* are not suitable for all purposes. They sometimes peel off, and are non-elastic. Whitehead's varnish, and the mastic varnishes of various formulae, have again superseded them for many purposes. During the war styrax was difficult to obtain, and rose in price to between 30s. and 35s. per pound. It is the non-drying constituent. It seemed to the writer to be an unnecessary waste of money to buy styrax when the common resin (*B.P.*) or colophony would substitute so well. The cost of resin is 8d. per pound as against 6s. 9d. for styrax.

The following formulae were devised, and have been in constant use for fifteen years, to the exclusion of the well-known Whitehead's varnish.

Pigmentum benzoin (benzoin varnish). Benzoin, 4 drachms; resin, 3 drachms; balsam tolu, 1 drachm; ether 0·720, 5 ounces.

Pigmentum iodoformi (iodoform varnish). Iodoform, 1 drachm; benzoin varnish, 10 drachms.

These formulae are effective, and are cheap to use. They do not retract the skin, but dry well and remain elastic. They are clean and antiseptic, and are mildly stimulating.—I am, etc.,

J. WICLIFFE PECK, Ph.C., F.C.S.

The Hospital for Sick Children, Great Ormond Street, Sept. 21st.

THE TERM "CONGENITAL"

SIR,—It seems to me that the application of this term should be revised. A disease such as syphilis can never be congenital in the truest sense. This term should be applied only to primary diseases, which, so far as our present knowledge goes, are inseparably associated with the germ-plasm of the individual.

I desire to suggest the use of the word "connatal" for the terms "ante-natal" and "post-natal" which are already widely current. Syphilis, therefore, which is acquired by inoculation of the spirochaete during the passage through the birth passages in labour is "connatal syphilis." It is said, moreover, that certain cases of this disease—for example, syphilitic iritis—may occur in the foetus *in utero*. This is "ante-natal syphilis." In both cases it is an acquired disease. The term "congenital," as applied to syphilis, is a relic of the days before the organism of the disease was discovered; and the latter, therefore, had to be classed with the true congenital diseases.

If what I have said is true, the term "congenital syphilis" should cease to be used. Similarly, ophthalmia neonatorum (when the organism is the gonococcus) is due to connatal gonorrhoea.—I am, etc.,

M. MELGRAVE.

Durham, Sept. 22nd.

RADIOLOGY AND THE RADIOLOGIST

SIR,—As we do our own screening and *x*-ray work here, and in most other sanatoriums, I have been greatly interested in your article and the correspondence.

From time to time I get specialist radiographers' films sent me with their readings attached, and I am always lost in amazement at the cavities found, and at such common phrases as "a heavy peri-bronchial infiltration of a beaded type throughout the upper part of the lung." Might I suggest an intensive campaign, conducted by the clinician, the radiologist, and the pathologist, the end of each case investigated being the post-mortem room. No one is certain of what a pleural ring means; some consider it a cavity, some a spontaneous pneumothorax, and others a pleuritis. Surely this enigma could be solved in the post-mortem room. The radiologist could use lipiodol to help him. Strong hospital committees would be able to insist on a post-mortem examination of any patient dying in their chest hospitals.—I am, etc.,

JAMES D. MACFIE.

Wingfield Sanatorium, Sept. 26th.

PERNICIOUS ANAEMIA

SIR,—I should be very grateful if any of your readers would refer me cases of pernicious anaemia for treatment at Guy's Hospital. Patients with septic complications or paralysis are not suitable.—I am, etc.,

L. J. WITTS.

Guy's Hospital, S.E.1, Oct. 5th.

ADENOIDS

SIR,—I am particularly anxious to obtain for display in our museum photographs of a case of adenoids, one showing the condition before operation and another taken a year or so later, to illustrate the mental and physical improvement that has resulted from treatment. If any reader has such, and would loan the same to me, I would have them copied and the originals promptly returned.—I am, etc.,

H. B. NEWHAM, Curator.

London School of Hygiene and Tropical Medicine (University of London), Keppel Street, W.C.1, Oct. 5th.

Obituary

G. WASHINGTON ISAAC, M.B., C.M.

We regret to announce the death of Dr. George Washington Isaac, which took place at his house in Gower Street, London, on September 24th, after a month's illness. He was born on January 18th, 1857, and from Clifton College went to study medicine at the University of Edinburgh, where he obtained the M.B. and C.M. degrees in 1882. After graduation he came to London and practised at first in Camden Town, removing some forty years ago to Gower Street. He was for many years medical officer to the Home and Colonial Training College for Governesses at Wood Green; also to the St. Pancras Female Orphanage, the St. Giles's Almshouses, and the Nurses' Lodge in Colosseum Terrace, Regent's Park. A strong individualist and devoted to the daily work of his profession, Dr. Washington Isaac won the esteem and affection of a wide circle of patients, who found in him a genial friend, as well as a trusted and skilful adviser. It has been said of him with truth that he gave himself unstintingly to his patients, always putting their interests before his own. He was long a Fellow of the Medical Society of London, and a member of the Westminster and Holborn Division of the British Medical Association. The funeral service at Golder's Green Crematorium on September 28th was attended by many friends and colleagues, the Association being represented by Mr. L. Ferris-Scott, Financial Secretary and Business Manager.

Mr. G. GORDON-TAYLOR, surgeon to the Middlesex Hospital, sends the following appreciation:

The death of Dr. Washington Isaac, at the age of 74, removes a familiar figure from the Bloomsbury district of London. Graduating at Edinburgh half a century ago, like many others he sought the arenas of the South, and built himself up a big practice in London. He was a most competent, pain-taking, kindly, and hard-working practitioner, dearly beloved by his patients, in whose welfare he never spared himself. His interest in motoring must have been as long-lived as that of any medical man,

and the small cars that he was accustomed almost invariably to drive himself were nearly as well known as was the owner. In latter years his one recreation was an interest in wireless, and he constructed for himself a fine piece of apparatus, in the mechanisms of which he took an absorbing interest. He was, however, essentially a hard worker, and it is characteristic of the man that during the war he took a commission in His Majesty's Forces. He was an excellent example of one whose years reached well into the seventies, yet whose energies were unabated, whose mind was acute, despite the fact that he never found time to take a holiday.

THE LATE SIR WILLIAM SIMPSON

Colonel W. G. King, C.I.E., I.M.S. (ret.), sends the following appreciation:

The obituary notice in the *Journal* of October 3rd concerning Sir William Simpson, C.M.G., conveys lucidly and sympathetically the fact that he was typically a sanitarian, in that he strove to marshal and utilize accumulated knowledge of all branches of euthenics for the prevention of disease. May I be permitted to afford further examples of the work he fulfilled in this direction. Thus, as editor of the *Indian Medical Gazette*, to secure interchange of opinions among medical men dealing with the diverse circumstances met in the huge area of India, it was at his suggestion, in October, 1893, and largely by his aid in organization, that the first Indian Medical Congress was assembled in 1894. The numerous annual meetings thus inaugurated have undoubtedly proved of much professional utility. Devotion to the practical application of hygiene necessarily left him little time for "research," as understood at the present day. Nevertheless, that aspect of sanitary science was not neglected, and hence I would recall as memorable work by him, that at a time when the profession held firmly the view that variola vaccine must revert to its original source when used on the human being, he proved experimentally (1884-85) the fallacy of that dogma. His evidence, although accepted by the Local Government Board of the period, was not published till the issue of the sixth report of the Royal Commission on Vaccination in 1897; and the facts consequently were not known to the men who in and after 1891 also dealt with the subject. In 1894, whilst health officer, Calcutta, in conjunction with Haffkine (who happened to be there in connexion with his now famous cholera vaccine), he collected data which tend markedly to demonstrate the connexion of cattle with Hindu social habits and the spread of cholera. To this subject I invited attention in my letter which appeared in the *British Medical Journal* of December 27th, 1930. On referring the subject to him in the month concerned, Sir William informed me that owing to his departure from India it had been impossible for him to further investigate the subject. Seeing that the Government of India in the period which has elapsed has annually provided liberal funds for research, there seems no sound reason why this highly important subject, which entailed much arduous labour by the investigators, has failed to secure attention. It certainly deserves a definite "yea" or "nay" in a country where, in the period 1914-23, within the British India area alone, there were recorded 3,154,908 deaths from cholera.

We regret to record that Dr. Herbert Arnott Eadie was killed in an accident to a motor tractor at Post Hill, Leeds, on September 27th. Dr. Eadie was born in Edinburgh in 1901, was educated at the Edinburgh Academy, and received his medical training in Edinburgh, where he graduated M.B., Ch.B. in 1922. After holding resident posts at the Royal Infirmary, Edinburgh, and at the Leeds Public Dispensary, he entered into general practice in Leeds in 1924, and very soon became well known both medically and socially in the city. He was a popular officer in the Territorial Army, and for the last four years had held a captaincy in the R.A.M.C. (T.A.) in the 146th Field Ambulance. A keen and true sportsman, he was fond of riding, shooting, golfing, and motoring. He was a man of charming personality, and many among his large circle of friends will have experienced in his sudden and tragic death a real sense of personal loss. His great popularity was manifested at his funeral, which was accorded full military honours. He leaves a widow and two young children, a daughter and a son.

The following well-known foreign medical men have recently died: Dr. Louis Goudard, a former president of the Société Médicale de Paris; Dr. Ducamp, professor of clinical medicine at Montpellier; Dr. A. Besson of Paris, author of a work on microbiological and serotherapeutic technique, now in its eighth edition; Dr. Piana, for twenty-five years director of the Radiological Institute of Genoa; and Dr. Hubert Arrowsmith, founder and past-president of the American Bronchoscopic Society, aged 68.

Universities and Colleges

UNIVERSITY OF LONDON

Honorary Degrees

A reception was held at the University on September 28th, to celebrate the centenary meeting of the British Association. On this occasion the degree of Doctor of Science *honoris causa* was conferred on the president of the association (General the Right Hon. Jan Christiaan Smuts, C.H., F.R.S.), and on the following distinguished members: Sir Frederick Gowland Hopkins, P.R.S., Sir Charles Scott Sherrington, O.M., G.B.E., F.R.S., the Right Hon. Lord Rutherford of Nelson, O.M., F.R.S., and, *in absentia*, Sir Joseph John Thomson, O.M., F.R.S.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Museum Demonstrations

The autumn course of museum demonstrations in the theatre of the College will commence on Friday, October 23rd, when Sir Arthur Keith will discuss specimens illustrating the nature and extent of the changes which have affected the jaws of English people in recent centuries. On October 30th he will explain specimens illustrating the anatomy of the pyloric sphincter in cases of hypertrophic enlargement, and on November 6th specimens illustrating the pathology of hydrocephaly. Mr. Cecil P. G. Wakeley will discuss primary bone tumours and secondary tumours of the bone on October 26th and November 2nd respectively. The course will terminate on November 9th, when Mr. R. Davies-Colley will demonstrate the borderline tumours of bone. The demonstrations, which are open to advanced students and medical practitioners, will be held at 5 p.m.

UNIVERSITY OF LONDON GRADUATES' ASSOCIATION

A communication addressed to the University of London Graduates' Association from Earl Beauchamp, announcing his resignation as Chancellor of the University, having been read at the meeting of the council of the association on October 2nd, it was resolved unanimously to invite Lord Moynihan of Leeds, President of the Royal College of Surgeons of England and a distinguished graduate of the University, to accept the association's nomination for the office of Chancellor.

It was further unanimously resolved, in view of the forthcoming General Election, that the association should again nominate Sir Ernest Graham-Little, the sitting member of Parliament for the University, as its candidate, and the council expressed gratification that he had declared himself a supporter of the National Government.

Medical Notes in Parliament

[From our Parliamentary Correspondent]

Parliament was prorogued on October 7th, and a Dissolution immediately followed, elections for a new Parliament being ordered for October 27th. At the end of the session the Foodstuffs (Prevention of Exploitation) Bill and the Sunday Performances (Temporary Regulation) Bill were considered.

National Health Insurance

Mr Chamberlain told Mr Oliver on September 24th that 515 approved societies and branches had included in their schemes of additional benefits Additional Benefit No. 16 under which special treatment for rheumatic diseases would be possible.

Mr L. D. Sutton (Parliamentary Secretary Ministry of Health) told Mr Stephen on September 30th that provision of a second medical opinion in cases of doubt whether an insured patient was incapable of work had been recognized as desirable since sickness benefit first came into operation. He could not therefore consider a suggestion for abolishing or reducing the regional medical office department and allowing panel practitioners to determine whether their patients were fit or otherwise without interference from an outside department.

Replying to Mr Stephen on September 30th Mr Sutton said that grants from the special expenses portion of the mileage funds in England and Wales were made when requisite to enable insurance doctors practising in sparsely populated areas to provide improved service for the benefit of their insured patients. Special conditions governing the division of such a grant for expenses were in operation when two or three doctors practised in a sparsely populated area.

Replying on October 1st to Sir Robert Young Mr Chamberlain said unemployed workers would not be automatically deprived of national health insurance benefits should the Public Assistance Committee under the means test deprive them of further unemployment benefit. So long as a person remained insured under the Insurance Acts he would continue to be entitled to benefits in accordance with the provisions of those Acts and would not be subject to penalties for arrears of contributions in respect of weeks for which satisfactory proof of unemployment was produced.

On October 5th Mr Chamberlain replying to Mr Rhys Davies stated that the cost of the regional medical service under the national health insurance scheme for the last five years was: 1926–27 £130 785; 1927–28 £156 721; 1928–29 £156 700; 1929–30 £164 886; and 1930–31 £184 036.

Tuberculosis Mortality

Replying to Mr Shepherd on October 1st Mr Chamberlain stated that the number of deaths from all forms of tuberculosis per cent. of the total population in England and Wales in each of the years 1911–30 was:

1911	0·1468	1921	0·1126
1912	0·1372	1922	0·1121
1913	0·1362	1923	0·1062
1914	0·1361	1924	0·1058
1915	0·1515	1925	0·1078
1916	0·1529	1926	0·0961
1917	0·1624	1927	0·0972
1918	0·1694	1928	0·0926
1919	0·1284	1929	0·0959
1920	0·1133	1930	0·0898

The figures for the years 1915–20 inclusive were based on civilian deaths and civilian population.

Foot and Mouth Disease

Sir J. Gilmour replying to Brigadier-General Brown on October 5th said that twenty-three cases of foot and mouth disease had been confirmed in Great Britain since August 1st last of which seven had occurred since September 1st. The most recent outbreak was confirmed on October 4th at Grafham (Huntingdonshire). Infected area restrictions were at present in force in three districts—namely, within areas of fifteen miles radius of Grafham (Huntingdonshire) and of Walsall (Staffs.) and an area covering five miles radius of two infected places in adjacent parishes in Pembrokeshire and Carmarthenshire. Since August 1st 375 cattle, 631 sheep, 514 pigs, and 1 goat had been treated with foot and mouth disease serum. The disease appeared in only one instance among treated stock in this period—namely, on August 30th—when five cattle went down out of a number of animals which had been inoculated with serum thirteen days previously. Replying to supplementary questions Sir J. Gilmour said that it was too early to form an definite conclusion as to the actual result of the serum treatment. He still considered that the best way to counteract the disease was by slaughter, and burning the carcases.

Exports of Indian Opium.—On September 28th Sir S. Hoare replying to Major Pole said that in 1926–27 26 254 592 ounces of opium were exported from India. In 1927–28 18 259 840 ounces were exported, in 1928–29 14 951 975 ounces, in 1929–30 13 392 800 ounces, and in 1930–31 9 558 480 ounces.

Milk Standards.—Mr Chamberlain told Mr Potts on October 1st that he could not introduce any legislation enforcing a definite bacteriological standard of milk and making it an offence for producers and retailers to sell milk not of the fixed standard.

Puerperal Fever.—Mr Chamberlain told Viscount Cranborne on October 1st that the theories of Mr Todd with regard to the prevention of puerperal fever submitted to the Ministry of Health had been referred to the Departmental Committee on Maternal Mortality and were still under its consideration.

Tuberculous Cattle.—On October 2nd Sir John Gilmour (Minister of Agriculture) stated that the cattle population of England and Wales in June 1931 was 5 849 776. In 1930 reports were made under the Tuberculosis Order 1925 on 15 008 premises containing 471 827 cattle. On these premises 177 425 cattle or 3 per cent. of the total cattle population were the subject of reports and 12 760 cattle were slaughtered in pursuance of the Order being 0·2 per cent. of the total cattle population.

Dust from Cement Mills.—The reports of the alkali inspectors of the Ministry of Health show that progress has been made in reducing the emission of dust from the cement factories on the banks of the Thames in Essex and Kent. No recent complaints have been received.

Pensions Claims.—Major Tryon states that during the twelve months ended last June 11 193 new claims outside the seven years limit were received by the Ministry of Pensions. In that time 13 000 claims were decided of which about 630 cases were admitted to pension and 22 were found to require not more than medical or surgical treatment.

Rate-aided Mental Patients.—On January 1st last there were 108 917 rate-aided patients in mental hospitals in England and Wales. On the same date 16 119 persons were in receipt of domiciliary medical relief while on June 27th last 13 218 persons were receiving this form of relief.

The Services

DEATHS IN THE SERVICES

Deputy Inspector-General Richard Edmund Bullup, R.N. (ret.), died at the Royal Naval Hospital, Bighi, Malta, on July 6th. He was educated at Trinity College, Dublin, where he graduated as B.A. and M.B. in 1876, and as M.Ch. in 1877. Entering the Navy as surgeon soon after he attained the rank of fleet surgeon on October 1st 1889, on retiring as deputy inspector-general on April 28th 1897.

Deputy Inspector-General Richard Gavin Pearson, R.N. (ret.), died at Southsea on July 9th. He was educated at Aberdeen, where he graduated as M.B. and C.M. in 1869. Entering the Navy soon after he attained the rank of fleet surgeon on November 14th 1882, and retired with the rank of deputy inspector-general on April 1st 1900. He served as senior medical officer in the Nile expedition of 1884–85, was in medical charge of the Naval Brigade during the Suakin campaigns of 1885 and 1886, and took part in the Soudan campaigns of 1885 and 1886, and was mentioned in dispatches by Commander Sir W. N. Hewett. He was in receipt of a Greenwich Hospital Pension.

Surgeon Captain James Duff Scott Milln, R.N. (ret.), died at Alverstoke, Hants, on August 28th. He was educated at Dundee and at Edinburgh University, where he graduated as M.B. and Ch.B. in 1897. Entering the Navy as surgeon soon after graduation, he attained the rank of surgeon commander on November 29th, 1911, and retired, with an honorary step of rank as surgeon captain, on November 10th, 1924. He served throughout the war of 1914-18.

Surgeon Francis Henry Spencer, Army Medical Department (ret.), died at Exeter on June 10th, aged 82. He was born at Chippenham, Wilts, in 1849, and was educated at King's and University Colleges, London, and Aberdeen University, where he graduated M.B. and C.M. in 1873, and M.D. in 1876. He took the M.R.C.S. and L.S.A. in 1871, entered the Army as surgeon in 1873, and was placed on half pay, on account of ill health, on March 1st, 1879.

Colonel John Archibald Hamilton, C.M.G., Bengal Medical Service (ret.), died in a nursing home at Bath on July 29th, aged 61. He was born on November 4th, 1869, the son of Robert Gordon Hamilton, Esq., cotton broker, Birkenhead, and was educated at Edinburgh, where he graduated as M.B. and C.M. in 1892. Subsequently he took the diploma in tropical medicine at the London School of Tropical Medicine in 1913. Entering the I.M.S. as surgeon lieutenant on January 29th, 1895, he became lieutenant-colonel on July 29th, 1914, was placed on the selected list for promotion on March 1st, 1921, and retired, with an honorary step in rank as colonel, on June 8th, 1922. He served in the China war of 1900, receiving the medal and clasp; and in the war of 1914-18, in France in 1914-15, and in Iraq in 1916-20, was mentioned in dispatches four times—in the *London Gazette* of January 1st, 1916, January 5th, 1919, February 12th, 1920, and May 21st, 1920—and, in addition to the medals, received the C.M.G. on January 14th, 1916. Subsequently he served in Kurdistan in 1919-20, and in Waziristan in 1920-21.

Medical News

The President and Council of the British College of Obstetricians and Gynaecologists have issued invitations to a dinner on Friday, October 23rd, at Grosvenor House, Park Lane, W.

The annual dinner of the Chelsea Clinical Society will be held at the Rembrandt Hotel, Thurloe Place, S.W., on Tuesday, October 20th, at 7.30 p.m.

The annual general meeting of the West Kent Medico-Chirurgical Society will be held at the Miller General Hospital, Greenwich, to-day (Friday) at 8.45 p.m., after which clinical cases will be discussed.

The Cockburn Memorial Lecture before the Child-Study Society will be given by Dr. A. F. Tredgold at 90, Buckingham Palace Road, S.W.1, on Thursday, October 22nd, at 6 p.m.; the title of the lecture is "Some observations on mental development."

Sir Richard Gregory will open, at 4 p.m. on Wednesday, October 21st, at the Science Museum, South Kensington, an exhibition illustrating modern research in the British glass industry. Besides the exhibition there will be lectures on Thursday afternoons dealing with the modern developments in optical glass, plate glass, electric light bulbs, and safety glass.

The next monthly clinical meeting for medical practitioners will be held at the Hospital for Epilepsy and Paralysis, Maida Vale, W.9, on Thursday, October 15th, at 3 o'clock, when Dr. Russell Brain will give an address on epilepsy. Tea will be provided. Those intending to be present are asked to send a card to the secretary.

The course in venereal diseases arranged to be held at the municipal clinic of the Salford Public Health Department has had to be postponed indefinitely owing to the illness of Dr. E. T. Burke.

A post-graduate course on renal and cardiac diseases is being arranged at Frankfort, under the direction of Professors Volhard and Schmieden. The fee is 25 marks. Further information can be obtained from the Medizinische Klinik, Eschenbachstrasse 14, Frankfurt-a-M.

A free post-graduate course on malignant tumours will be held at the Medical Faculty of Tübingen University from October 26th to 28th. The programme can be obtained from the dean of the faculty.

The thirty-eighth Italian Congress of Surgery will be held at Bari from October 18th to 21st, under the presidency of Professor G. Righetti of Bari. The principal subjects for discussion will be the syndrome associated with the right abdomen, introduced by Professor N. Leotta of Palermo; and acute and chronic pancreatitis (in conjunction with the Italian Society of Internal Medicine), introduced by Professor G. Tunisi of Genoa.

The thirty-seventh Italian Congress of Internal Medicine will be held at Bari from October 13th to 21st, when the following subjects will be discussed: diabetes, introduced by Professor L. Zoia; the onset and evolution of pulmonary tuberculosis, introduced by Professors C. Gamna and A. Omodei-Zurini; acute and chronic pancreatitis, introduced by Professor Gasbarrini; and malaria and tuberculosis in the army, introduced by Colonel V. de Bernardinis.

The annual meeting of the International Society of Medical Hydrology will take place in Amsterdam at the American Hotel from October 31st to November 2nd. Discussions will be held on the influence of chill in the causation of disease, opened by Professors Schade and van Loghem, and on factors in marine treatment, opened by Professor Moll and Dr. Häberlin. Arrangements have been made for visits and demonstrations at various clinics and objects of interest in the city. A limited number of places are available for non-members, including ladies; full particulars can be obtained from the society's office, 55, Wellington Road, London, N.W.1.

In the annual report of the department of neurology and psychiatry of the Severance Union Medical College, Seoul, Korea, Dr. C. I. McLaren commends warmly the epidural injection method for the treatment of sciatica and trigeminal neuralgia. He compares the scope for neuro-psychiatry in Korea with that in Europe and America, and mentions the reappearance of beri-beri among Koreans with the recent introduction of machine methods of preparing rice. The majority of cases treated during the year were neuroses and psychoneuroses; Dr. McLaren prefers the therapeutical methods of Dejerine and Adler to those of Freud.

The Fellowship of Medicine and Post-Graduate Medical Association announces that a lecture on cancer will be given in the Medical Society of London lecture room on October 14th, at 4 p.m., by Mr. W. Sampson Handley; no fee. In connexion with the series of evening lectures for the M.R.C.P., Dr. L. J. Witts will lecture on gastric and duodenal ulcer, on October 12th, and Dr. R. D. Lawrence on diabetes, on October 14th, both at 8.30 p.m.; fee for each lecture, 10s. 6d., payable at lecture room (or £6 6s. for series of sixteen lectures). A post-graduate demonstration will be given by Mr. J. P. Lockhart-Mummery at St. Mark's Hospital, City Road, on October 12th, at 2.30 p.m.; no fee. "The management of difficult cases of feeding" will be dealt with by Dr. Eric Pritchard at the Infants Hospital, Vincent Square, on October 16th, at 3.30 p.m.; no fee. The following courses will begin on Monday, October 12th: in medicine and surgery, at the Prince of Wales's Hospital, Tottenham, occupying the whole of each day for two weeks, fee £5 5s. or £3 3s. for either week; in dermatology, at St. John's Hospital, Leicester Square, daily clinics at 2 and 6 p.m. and lectures at 5 p.m., on Tuesdays and Thursdays, fee £1 1s. for four weeks; in diseases of the heart, at the National Heart Hospital, occupying the whole of each day for two weeks, fee £7 7s. Forthcoming courses include paediatrics, at the Hospital for Sick Children, Great Ormond Street, from October 19th to 31st, in the mornings only, fee £5 5s.; medicine, surgery, and gynaecology, at the Royal Waterloo Hospital; neurology, at the West End Hospital for Nervous Diseases; and ophthalmology, at the Royal Westminster Ophthalmic Hospital. Copies of syllabuses on application to the Fellowship of Medicine, 1, Wimpole Street, W.1.

Prophylaxis of Lumbago

"B S" writes, in reply to "S L" (October 3rd, p 637) The answer is warmth, dryness, rest, exercise, and diet I would suggest a dry, warm house, well ventilated, dry bedding (feather beds absorb damp, and should be periodically warmed all day by the fire), a sufficiently long indoor jacket, a waistcoat lined with flannel at the back, moderate walking exercise, and occasional rests, lying flat on a firm, level bed, very moderate use of sugar and carbohydrates, massage once or twice weekly, and a Turkish bath every two or three weeks A short course of resorcinol, or some other urinary antiseptic, is often found beneficial

Dr H Fergil Woods (London, W) writes, in reply to "S L" The recurrent attacks suggest a lesion of the sacro iliac synchondrosis, or of a lumbar vertebra, and manipulation might entirely do away with recurrence of attacks Relief at the time of an attack might be gained by the administration of rhus toxicodendron, which has an immediate effect in some forms of lumbago I can speak for the efficacy of both the above mentioned methods of treatment, after a score of years' experience of them

Income Tax

Depreciation or Cost of Renewal of Car

"G P" inquires which is better—to claim depreciation annually, or only cost of replacement when the car is exchanged

*** Depreciation annually If the car is not renewed—for example by reason of retirement—the allowance is entirely lost if cost of renewal is relied on for redress Further, the allowance of depreciation does not prevent a claim for 'obsolescence" being made for a deduction of the cost of the car less the amount received for it, together with the aggregate of the depreciation allowances For example car cost £250 £96 allowed for depreciation in three years car sold for £75, when another purchased in place of it, obsolescence allowance as an expense of year of sale would be £250 − (£96 + £75 =) £171—that is, £79

Liability on New Basis

"Member B M A" asks what tax will be payable by him on a pension of £634 He is a bachelor, 66 years of age, and has a dependent relative, his sister acts as housekeeper

*** Assuming that the pension ranks as "earned income" his liability under the second Budget will be as follows

		£	£
£634 less 1/5 = £127 earned relief			507
Personal allowance	.	100	
Dependent relative allowance	..	25	
Housekeeper allowance	..	50	
			£175
			£332

Tax payable

£175 at 2s 6d	= £21 17	6
£157 at 5s	= £39 5	0
£332	£61 2	6

Car Replacement

"D M J" has had several cars during the past few years, and the allowance for maintenance has been on the basis of cost of replacement" In 1928 he had two cars but one was not satisfactory, and he bought a third Not being able then to obtain what he considered a reasonable offer, he retained it for a time, and ultimately sold it two and a half years later During that time all three cars were licensed and used The inspector of taxes declines to make an allowance for the loss on sale on the ground that the car bought in 1931 was not a "replacement"

*** The essential point seems to us to be whether, in fact, the transaction was intended to be—as it ultimately proved to be—a replacement If "D M J's" intention was to add to his car equipment and was subsequently changed, the inspector's view would be correct—the subsequent change would not affect the real nature of the original transaction But it is obviously not essential that the sale of the replaced asset should be effected immediately, and, although the interval was quite unusually long in this case, we consider that there is no legal bar to the allowance, and, further, that the local commissioners or the Board of Inland Revenue would be impressed with the obvious equity of our correspondent's case It is, of course, a pity that "depreciation" was not claimed year by year

LETTERS, NOTES, ETC.

Maggots in Wounds

Dr Arthur J Turner (Lee-on-the-Solent) writes During my work in hospitals on the North-West Frontier of India I met with several cases of bone disease caused by maggots Under the surgeon's full control it may be true, as Dr Bate concluded, that "maggots, by their digestive action clear away the minute fragments of bone and tissue sloughs caused by operative trauma." But sad indeed were the cases to which I refer, where, through flies having entered the patient's nose or ear, eggs had been deposited in the nasal or aural cavities, and the resulting maggots were at work digesting, uncontrolled, the mucous membranes fibrous and bony tissues, and even the brain of the still conscious and functioning human being In the worst case (one can never forget it) parts of the face, nose, mouth, skull and brain had been eaten away, presenting a terrible spectacle Spirits of turpentine in aqueous solution, 20 minims to a pint of water, was the most successful in reaching and killing the maggots, and patients in an early stage of nose or ear destruction were cured, but the above case of extensive attack was brought in too late, and drastic search under an anaesthetic proved unavailing to reach the furthest areas to which the maggots had penetrated The patient died a few days later.

Medical Care on Passenger Ships

Dr E H Price (Brighton) writes: I have recently returned from a voyage to Canada on one of the Cunard liners and I was much impressed by the arrangements now provided for the sick at sea There was excellent hospital accommodation, including isolation and special wards The dispensary was large, and contained all the medicines serums, and vaccines one could possibly require Everything was scrupulously clean, and the surgical instruments were of the latest design and in good order The ship carried a trained nurse and dispenser. A very accurate account of illnesses and accidents occurring on the voyage had to be kept As one who acted for many years as medical superintendent of a large hospital, I was much impressed with the efficiency of this small medical unit afloat Doctors who recommend sea voyages for their patients can rest assured that they will be well cared for in these days of modern ocean travel

Advantages of Home Spas

Mr F J C Broome, general manager of wells and bath at Harrogate, writes At the present time, when every pound spent abroad reacts unfavourably on the financial situation I would draw the attention of physicians who may be contemplating sending patients to foreign spas to the advantages of home spas, where all the treatments obtainable abroad are administered The patient's prescription is rigidly followed, and his comfort is a matter for careful consideration by attendants more highly qualified and intelligent than those at foreign centres

Imported Diathermy Apparatus

Victor X-Ray Corporation Ltd, of Cavendish Place W 1 writes Your readers will perhaps be interested to learn that there is no duty upon imported diathermy apparatus as a whole, the only part of such machines subject to duty being any meters containing permanent magnets Rarely does this duty exceed 2s or 3s

Fencing

Dr A E Finckh of the Sydney Clinical Research Laboratories has sent us an English edition, which he has prepared for the use of the members of the Sydney Eppée Club of the rules governing fencing displays and competitions as issued by the International Fencing Federation The booklet purports to be an interpretation rather than an exact translation of the French text, and should be of interest to members of hospital fencing clubs in this country A copy has been placed in the Library of the British Medical Association.

Vacancies

Notifications of offices vacant in universities medical colleges and of vacant resident and other appointments at hospitals will be found at pages 51, 52, 53, 56, 57, and 58 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 215

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

311 Prophylaxis against Pneumonia

A. J. ORENSTEIN (*Journ. Med. Assoc. South Africa*, June 13th, 1931, p. 339) comments on his fourteen years' experience of the inoculation of native mine workers on the Witwatersrand against pneumonia. In 1911 the mortality from this cause among the natives was over 12 per 1,000, and in subsequent years there was an apparent fall, but reasons are given for doubting the real value in this connexion of prophylactic vaccination. In 1929 inoculation was discontinued in certain mines, and the subsequent history there did not suggest that any special benefit had been conferred by the previous vaccination against pneumonia. A contention that the clinical type of this disease had radically changed is examined by the author, and shown to be unjustified. No evidence emerged that prophylactic inoculation had diminished the attack rate in the early period of the natives' service in the mines. Orenstein reports also that study of the experimental work undertaken before the wholesale immunization of natives was attempted reveals that the results were by no means conclusive; only one experiment (in 1914) could really be considered encouraging. He concludes that in view of the probable existence of a large number of types of pneumococci, and the feebleness of the immunity conferred even by an attack of pneumonia, the possibility of effective prophylactic immunization appears to be very remote.

312 Early Nephritis in Scarlet Fever

E. ASHWORTH UNDERWOOD (*Brit. Journ. Child. Dis.*, April–June, 1931, p. 114), who records an illustrative case, remarks that the onset of true nephritis occurs generally about the second or third week of the disease, although febrile albuminuria may develop very much earlier. He quotes a case reported by Priest in 1927 in which nephritis was present from the onset of the disease, and ended in recovery. His patient was a girl, aged 16, who developed acute haemorrhagic nephritis on the second day, if not earlier, of an ordinary attack of scarlet fever, which was not treated by scarlatinal antitoxin. The tonsillitis showed a definite recrudescence during each of three attacks of tonsillitis in convalescence. On her discharge from hospital after 183 days' residence the urine had been normal for a fortnight. Four years later, however, the patient was reported to be suffering from chronic nephritis. Underwood suggests that the *Streptococcus scarlatinae* caused the initial nephritis, which was of a mild glomerular type, and that an acute interstitial nephritis supervened, which ultimately became chronic and involved other elements of the kidney.

313 Axillary Pleurisy after Artificial Pneumothorax

A. VITON (*Arch. Méd.-Chir. de l'Appareil Respir.*, 1931, vol. vi., No. 1, p. 42) has seen four cases of a form of pleurisy, following artificial pneumothorax, which he terms "axillary." In each case pneumothorax had been induced for an active tuberculous lesion. Three of these patients had lived at high altitudes for a long time. Three were women, and the axillary pleurisy was on the left side; the male patient had right axillary pleurisy. Viton defines two distinct types. In three patients the axillary symptoms appeared during resorption of a generalized pleurisy, following artificial pneumothorax. In the other form a localized axillary pleurisy occurred without a preceding effusion into the general pleural cavity. The physical, chemical, and cytological characteristics of an axillary pleuritic exudate are similar to those of an ordinary effusion following artificial pneumothorax. Axillary pleurisy is one of the forms of localized pleurisy ("pleurésie cloisonnée") described by French writers; it recommends no special treatment, except that he endeavours to promote pulmonary collapse. As is usual in these cases, the pleural coefficient of gaseous absorption diminishes considerably, hence the intervals between insufflations can be increased. Treatment should not be restricted to one method, but should be selected according to the necessities of the case or the type of the disease—for example, tuberculin, antigen therapy, or sanocrysin should be used when indicated.

314 Meningitis due to Ascaris lumbricoides

A. CHALLAMEL (*Bull. Soc. de Thér.*, June 10th, 1931, p. 184), who records an illustrative case, emphasizes the clinical and cytological resemblance of meningitis caused by worms to tuberculous meningitis, and points out that owing to the formation of toxins the nervous symptoms may develop after the expulsion of worms in a macerated condition. Challamel's patient was a girl, aged 6 years, who suddenly developed left facial paralysis, followed the next day by symptoms of meningitis. The cerebrospinal fluid, however, was clear, though under pressure; it showed a leucocytosis, 50 per cent. of the cells being polymorphonuclears, and the remainder lymphocytes. A diagnosis was then made of incipient poliomyelitis, but after expulsion of a dead *Ascaris lumbricoides* was changed to that of helminthous meningitis. The temperature fell and Kernig's sign disappeared, although the facial paralysis persisted for a month.

315 Diagnosis of Meningococcaemia

S. MCLEAN (*New York State Journ. of Med.*, June 15th, 1931, p. 684) emphasizes the value of smears from purpuric lesions in cases of endemic purpuric meningococcal bacteraemia. About 11 per cent. of patients admitted to the Babies' Hospital, New York, with meningococcal infections showed purpuric eruptions, the youngest was aged 46 days and the oldest 7 years. Out of seventeen cases in which an effort was made to find meningococci in the haemorrhagic skin lesions, organisms were discovered in twelve.

Surgery

316 Malignant Tumours of the Bladder

R. DARGET (*Bordeaux Chirurgical*, July, 1931, p. 189) summarizes the results of radium therapy in twenty-three cases of malignant tumours of the bladder. It is pointed out that extensive surgical intervention such as partial cystectomy, hemi-cystectomy, with or without nephrectomy, or total cystectomy, has now been abandoned; operation is limited to cystostomy, which makes the use of physical agents possible. Electro-coagulation of the exposed bladder, and radium therapy by implantation of needles or tubes of radium, are the two methods of treatment; the author favours the latter procedure. Of the twenty-three cases treated by radium therapy, five patients died following the operation, but were all very unfavourable cases. Five other patients died a few months after operation from varying causes, such as pneumonia, cerebral haemorrhage, and recurrence of the tumour, but the remaining thirteen made good recoveries and were still well at the end of varying periods of from three months to seven years. In each case the malignancy of the neoplasm was confirmed by histological examination. The aim of the radium therapy is the destruction of the tumour and prevention of recurrence, and it is important that as little discomfort as possible should be felt by the patient during the application of the radium, and details of technique which render this more tolerable are given. The time for the needles to be left in position depends on the condition and situation of the tumour. For accessible tumours which are well exposed and well defined the duration of the application should be from

five to six days, but for grave ulcerated tumours which are badly placed in the bladder the radium must be left in place for seven days. The results from this form of treatment of malignant tumours of the bladder encourage the author to hope that it will be more widely adopted.

317 Congenital Dislocation of the Hip

In a review of congenital dislocation of the hip, M. C. Scholder (*Rev. Méd. de la Suisse Romande*, June 25th, 1931, p. 467) discusses at some length its pathogeny, due chiefly to the intrauterine position of the foetus and to the anatomical relations between the foetal cotyloid cavity and the femoral head. The condition is frequent in the white races, but rare in the black, and does not occur in animals; it predominates in females (88 per cent.). The reason for these differences is explained. Until the sixth month of foetal life the cotyloid cavity is hemispherical, its index (the ratio between the depth and diameter of the cavity) being 0.51; at birth the cavity is flattened, with a lower index, and admits only about a third of the femoral head. After birth the depth of the cavity and the index progressively increase till in adults two-thirds of the head is contained in the cavity. It is shown that during foetal development, owing to the increasing pressure of the uterine walls, there is a posterior displacement of the head of the femur, with ante-torsion of its neck, the latter being the more serious. The slightest exaggeration of these factors results in dislocation. The instability of the hip and the danger of dislocation increase as parallelism between the plane of the opening of the cotyloid cavity and the axis of the femoral neck is established; if parallelism is reached, dislocation becomes inevitable. The diagnosis of this condition from the clinical and radiological signs is usually easy. Orthopaedic treatment should be instituted early, and before the age of 4. After this age the muscular and capsular resistance increases, and reduction becomes more difficult; after 15 years it is almost impossible.

318 Injection Treatment of Varicose Veins

F. Maignon, C. Grandclaude, and M. Lambret (*Presse Méd.*, June 17th, 1931, p. 889), while studying the effects of injecting glycerin intravenously in dogs, discovered by chance the powerful sclerosing action of this reagent, and have elaborated a technique which they have used with great success in man. A first dose causes no trouble or apparent effect, but subsequent doses at the same point between the fourth and tenth days produced in all cases a very marked sclerosis, accompanied by the painless obliteration of the veins. There were neither local nor general reactions, and healthy patients were able to continue their occupations. The first injection results in sensitization of the vein wall; this begins to appear after about twenty-four hours, and is followed by a desensitization after about a fortnight. A preliminary dose of 5 to 10 c.cm. of a 50 per cent. solution of glycerin in distilled water is first injected through a suitable needle, and this is usually followed by one or two injections six days later of a 75 per cent. solution. All the cases were quite successful, and became free from disability; five are reported in detail. The patients' ages ranged from 50 to 77 years; the general state was poor and the health unsound, especially as regards the heart and lungs.

319 Digital Examination in Rectal Disease

F. C. Smith (*Med. Journ. and Record*, June 17th, 1931, p. 575) comments on some cases referred to him for treatment without a previous adequate local examination. In a woman diagnosed as suffering from haemorrhoids a large post-anal ulcer was seen as soon as the buttocks were pulled apart; there were no piles. Another woman had been treated for persistent diarrhoea for three months; a large carcinoma of the rectum was found within reach of the index finger. In a child treated for haemorrhoids a rectal polyp proved to be the cause of the haemorrhage. A man believed to have an acute rectal abscess was shown by digital examination to have a small chicken-bone stretched across the anus. An "ischio-rectal abscess" in a man was by a digital examination revealed as an external thrombotic haemorrhoid.

Therapeutics

320 Thiocyanate Therapy in Hypertension

W. G. Egloff, L. H. Hoyt, and J. P. O'Hare (*Journ. Amer. Med. Assoc.*, June 6th, 1931, p. 1941), as the result of treating a controlled series of hypertensive patients with potassium and sodium thiocyanate, conclude that this line of therapy is disappointing and disagreeable. Of their 25 ambulatory patients, all of whom had previously been under observation for two to ten years, 12 had primary hypertension, 11 had hypertension with hypertensive heart disease, and two had hypertension with moderate renal involvement. All other medication having been suspended, the thiocyanate was administered in diminishing doses for three weeks. The potassium salt was early abandoned in view of the distressing weakness and nausea that ensued. The sodium salt was given in an 8 per cent. aqueous solution. During the first week 1 gram was administered daily; in the second week the dose was reduced to 0.6 gram; and in the third week only 0.3 gram was taken. Eight patients discontinued the treatment after the first week, owing to the unpleasant results, and without any definite lowering of the blood pressure. Only 2 out of the 25 derived any benefit, and in their cases the improvement was not outside the limits of temporary diminution which sometimes occurs in hypertension even without medicinal administration. The headache, dizziness, and nervousness were unaltered in all the remaining cases. Every patient complained of nausea, and sometimes vomiting, commencing two to five days after the treatment started. Other common symptoms were diarrhoea, increased nervousness, and apprehension, with ringing noises in the head. One patient developed disorientation as to time and place. In view of these findings the authors conclude that thiocyanate therapy cannot be commended in hypertension.

321 Atropine in Encephalitis Lethargica

E. Schenk (*Münch. med. Woch.*, July 10th, 1931, p. 1177) records ten cases of encephalitis lethargica in patients aged from 20 to 53, in which good results were obtained by the long-continued administration of atropine, commencing with three drops of a 1/4 per cent. solution, the dose being increased daily by two drops. G. Arghiris (ibid., p. 1183) claims to have obtained complete cure in one case and considerable improvement in three others by use of the following method. An injection of 2 c.cm. of a 40 per cent. sterilized solution of urotropine is given intrathecally on the first day, and 10 units of insulin subcutaneously; three days later 5 c.cm. of urotropine and 15 units of insulin are administered, the same treatment being continued every three days until 20 units of insulin have been injected. In the case which recovered twenty lumbar punctures were performed, and in the other three, five to twelve. The treatment was combined with massage, light baths, diathermy, and tonics, such as arsenical preparations, or sedatives such as luminal or gardenal.

322 Treatment of Addison's Disease

C. H. Greene and L. G. Rowntree (*Proceedings*, Staff Meetings, Mayo Clinic, May 20th, 1931, p. 305) report further results from treating Addison's disease with the cortical hormone of Swingle and Pfiffner, with special reference to the chemical and metabolic changes, which they have found to be very similar to those reported in suprarenalectomized animals. Considerable doubt remains, however, as to the advisability of accepting chemical or metabolic changes in animals as valid criteria for the standardization of commercial preparations of this hormone. In recording the results of treating patients, moreover, it is necessary to exclude the influence of secondary effects which are not properly attributable to suprarenal insufficiency. The best methods of administration and the correct dosage have not yet been established. In 22 cases of Addison's disease, so treated, excellent immediate results followed in 17, some of the failures being possibly due to inadequate dosage. The clinical

improvement associated with this treatment comprises: disappearance of the anorexia, nausea, vomiting, and pain; return of healthy hunger and of the normal gastro-intestinal activity; relief from fatigue and insomnia; increase in weight, strength, endurance, blood pressure, and resistance to infection; decreased pigmentation; a more hopeful outlook, and a return to work. In treatment it is important to secure physical and mental rest, an adequately fluid diet, arrest of the dehydration, and employment of the Muirhead regimen when cortical hormone therapy is impossible. The inability of Swingle and Pfiffner to supply further material for clinical investigation has necessitated the authors making use of the product supplied by Parke, Davis, and Co., which is now being administered in close co-operation with the two previously mentioned originators of this special hormone therapy in Addison's disease. They add that the dramatic improvement, characteristic of cases treated by the first-named product, is now less notable, and that it is uncertain as yet how far the good results gained more slowly are attributable to the newly tried extract, or to the part played by the exhibition of glucose, water, and salt. Clinical idiosyncrasies in the later series of patients may also be concerned.

Anaesthetics

323 Effect of Anaesthetics on the Blood Lactic Acid

Among the metabolic effects following the administration of anaesthetics, hyperglycaemia and increase of lactic acid in the blood are known to occur. The latter also occurs in cases of liver insufficiency, and whenever there is a shortage of oxygen in the tissues; anaesthetics may produce either condition. In order to demonstrate minute disturbances of carbohydrate metabolism, or slight degrees of hepatic insufficiency, W. Seebening (*Schmerz Narkose-Anaesthesie*, June-July, 1931, p. 104) has studied the blood lactic acid curve following the intravenous injection of sodium lactate solution, corresponding to 4 grams of lactic acid. Blood is collected five, twenty, thirty, and sixty minutes after the injection. In normal persons the blood lactic acid is 7 to 13 mg. per 100 c.cm., and after the injection of 4 grams of lactic acid it returns to normal within 30 to 60 minutes. Operations tend to raise the lactic acid content, the amount of increase depending upon the disease and the condition of the patient, but above all on the type of anaesthetic used. Using the lactic acid tolerance test, as just indicated, the author found normal values during local or spinal anaesthesia, whereas during ether or avertin anaesthesia the blood lactic acid figure was increased, and the return to normal after injection was delayed. Even three or four days after the anaesthetic, when the initial blood lactic acid was within normal limits, the curves showed a diminished capability of the organism to deal with lactic acid.

324 Nupercaine in Spinal Anaesthesia

Despite the fact that the toxicity of nupercaine appears to be twenty times as great as that of procaine, E. L. Keyes and A. M. McLellan (*Journ. Amer. Med. Assoc.*, June 20th, 1931, p. 2085) conclude that its advantages outweigh its disadvantages. They report a series of 215 inductions of anaesthesia by nupercaine, the dose being 2 c.cm. of a 1 in 200 solution in spinal fluid. A preliminary subcutaneous injection of morphine and scopolamine is given half an hour before the patient is due in the operation theatre. A subcutaneous injection of 50 mg. of ephedrine hydrochloride follows just before the nupercaine is slowly introduced into the spinal canal, this being effected between the third and fourth lumbar vertebrae, with the patient in a sitting position. Additional anaesthesia was necessary for pain in 16 cases. The fall of blood pressure seemed to be less than when procaine is used; nupercaine anaesthesia is relatively slightly delayed, more intense, and from three to six times as lasting. The minimal blood pressure is reached always within half an hour. Nupercaine has also been used successfully in 1,000 solution for infiltration anaesthesia in such operations as cystotomy, circumcision, hydrocele, epididymectomy, and abscess opening. The authors do not commend the employment of a mixture of procaine and nupercaine. They encountered no evidence of intoxication with nupercaine, even in patients who had been previously rendered toxic by procaine.

325 Extra-ocular Muscle Paralysis following Spinal Anaesthesia

K. R. Fawcett (*Minnesota Med.*, July, 1931, p. 648) records two cases of unilateral abducens paralysis following spinal anaesthesia. The complication is rare, only five cases having been reported in a series of 2,000 spinal anaesthesias, and its etiology and peculiar affinity for the external rectus as compared with the other ocular muscles is as yet unexplained. The abducens nerve, however, occupies a very superficial position in relation to the fourth ventricle, which communicates directly with the subarachnoid space into which the anaesthetic is injected and it has been shown experimentally on dogs that the anaesthetic agent frequently reaches the medulla. If the strabismus is due to a mild meningitis the divergent type would be expected, but the type following spinal anaesthesia is usually convergent. The onset varies from three days to three weeks, and most cases clear up spontaneously in three weeks. In Fawcett's first case paralysis of the right external rectus with slight photophobia, vertigo, and headache, developed on the thirteenth day after operation, and had entirely disappeared thirteen days later. In the second case the squint occurred on the twelfth day, and persisted with but slight improvement for seventeen months. Owing to its tendency to clear up spontaneously, treatment of this condition should be conservative, and any operation postponed for at least eighteen months. The paralysis occurs more often with stovaine than with novocain.

Obstetrics and Gynaecology

326 Amaurosis during Pregnancy

B. H. Swift and A. L. Tostevin (*Med. Journ. Australia*, May 23rd, 1931, p. 632) report a case of increasing blindness during pregnancy; although no other sign of toxaemia was discoverable, it was decided to empty the uterus, and the vision rapidly returned to normal. There was a typical history of gradual diminution of vision at about the fifth month of pregnancy, with early loss of colour vision, and tenderness on moving the eyes. Repeated examination of the visual fields excluded the possibilities of hysteria and malingering. No toxic foci were detected in the cranium or elsewhere, and no evidence was obtained of syphilis or renal disease. The authors remark that increasing blindness or dimness of vision during pregnancy is usually a sign that the patient is becoming toxaemic, even though the usual signs of this condition are absent. Blindness often precedes the convulsion in commencing eclampsia, and usually clears up as soon as the uterus is emptied. It is attributed to toxic poisoning of the ganglia and optic nerves, and atrophy may ensue in the authors' case there had been slight dimness of the vision towards the end of a previous pregnancy, which had, however, terminated naturally, a healthy child being born.

327 Diagnosis of Gonorrhoea

L. Izwojnicka and T. Zawodziński (*Gynécol. et Obstét.*, June, 1931, p. 496) report the results of a comprehensive investigation of the complement-fixation test in the diagnosis of gonorrhoea in women which has been in progress since 1926 at the University of Warsaw. They emphasize the importance of using a uniform antigen, and commend those of Crostu and Owers. In technique they followed the method described by Besredka for the deviation of complement in tuberculosis; 1,495 tests were performed to discover whether the test was specific, and how rapidly the reaction disappeared in the blood of

patients who had been treated for gonorrhoea. In order to prove the specificity of the reaction a number of men were examined and tested because of the greater facility in proving the presence or absence of gonococci locally. The authors found that during the first three weeks after infection the reaction was negative in half the number of cases, but after the twenty-first day the results were almost uniformly positive (94.6 per cent.). As a control for this investigation 831 cases in which *a priori* gonorrhoea was not suspected were tested. The results were negative in 97.6 per cent. cases. The authors therefore conclude that they can state that the deviation of complement *in gonorrhoea* is specific. They found, further, that it remained specific even when the serum gave a positive Wassermann reaction. A small dose of gonococcal vaccine given within three months before the test would cause a positive deviation of complement; in the majority of cases the reaction became negative about one month after clinical cure. A positive reaction indicated, therefore, that the patient actually had, or at some previous period (not far distant) had had, an attack of gonorrhoea, or had been given a dose of vaccine some time during the three previous months. A negative reaction showed that: (1) infection was not present, or was too recent to have produced antibodies; or that (2) there was no ability to produce antibodies against gonococcal infection; or that the infecting dose was too small to give rise to antibodies; or that a pre-existing infection had terminated. The authors conclude that the value of a positive complement-fixation reaction has been demonstrated in the case of gonococcal infection in women.

328 Treatment of Menstrual Disorders

A. Lafront and H. Fulconis (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, April, 1931, p. 243) have made subcutaneous injections, in doses up to 8 c.cm., of the heated, filtered, and centrifugalized urine of pregnant women near term, into patients suffering from menstrual disorders. They thought that a therapeutic effect might ensue from the large amounts of folliculin which the urine contains towards the end of pregnancy. No response was obtained in patients with uterine deviation or ovarian cysts, but menstruation returned in three patients, aged about 30, who were suffering from secondary amenorrhoea. Local reactions to the injections were absent; general reactions were absent or slight. Urine of early pregnancy has been used by Zamkoff, who has reported some successful results in menstrual dysfunction, and attributes them to the anterior hypophyseal hormone.

Pathology

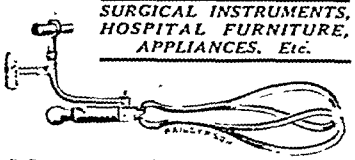
329 The Effect on Bone of Toxic Doses of Irradiated Ergosterol

R. Soeur (*Presse Méd.*, July 4th, 1931, p. 1003) undertook an experimental study on 11 adult rats, and 9 young guinea-pigs with one adult. To the guinea-pigs, which were of an average weight of 250 grams, were given daily doses of from 0.4 c.cm. to 7.5 c.cm. of the oily solution of irradiated ergosterol. They were kept under observation from 4 to 35 days. General results observed were: (1) an arrest of growth in all the animals; (2) loss of weight; (3) a series of morbid symptoms such as loss of appetite, diarrhoea, increased respiration, loss of vivacity, and loss of hair; (4) hypercalcaemia and hyperphosphataemia; and (5) the presence of deposits of calcium in the kidney, aorta, heart, and more rarely in the lung, stomach, or intestine. The principal phenomena observed in the bones were an arrest of the process of ossification, and a simple osseous reabsorption causing pathological fractures. Intense vascularization, and an aseptic necrosis of the bone marrow, were present. The adult rats were given daily doses of from 0.4 c.cm. to 2.7 c.cm. The general results were of the same order as those seen in guinea-pigs, but the rats showed greater sensitivity. In addition there were small haemorrhages at the nasal orifices, and round the eyes. The adult guinea-pig showed results intermediate between the young guinea-pigs and the adult rats. In conclusion Soeur finds that irradiated ergosterol does not act by stimulating the action of the parathyroids. It appears to act directly on the bone by a process of hypervitaminosis, or a simple toxic action, or possibly an intoxication resulting from impurities of the product.

330 Determination of Hydrogen-ion Concentration of Nutrient Agar

M. W. Lisse, O. G. Jensen, and R. P. Tittsler (*Journ. of Bacteriol.*, June, 1931, p. 383) have compared the colorimetric and the potentiometric methods for estimating the hydrogen-ion concentration of nutrient agar. The agar was diluted to varying degrees with distilled water after autoclaving; this prevented it from setting when it was cooled, and enabled potentiometric methods to be used. With the quinhydrone electrode a drift in potential occurred, which rendered the readings lower than those taken with the hydrogen electrode. Comparison of the results obtained by the hydrogen electrode and bromthymol blue showed remarkable agreement, indicating that bromthymol blue does not exhibit either salt or protein errors in nutrient agar. It was found that the agar medium could be diluted seven times without altering the *p*H; further dilution led to a slight fall. For routine determination of *p*H it would therefore appear as if the colorimetric method, using bromthymol blue, should give results of a fairly high degree of accuracy. The dilution of the agar has two great advantages: it prevents the medium from setting, thus enabling the readings to be taken at room temperature, and it renders the determination of colour changes very much more easy.

331 Fungus Infection of Sweat



O. L. Levin and S. H. Silvers (*Arch. Derm. and Syphil.*, June, 1931, p. 1094), realizing that sweat affords an excellent culture medium and is therefore probably an active factor in spreading infection, undertook experiments to prove the relationship between hyperhidrosis and fungus infections. Since the feet are more frequently involved by dermatophytosis than other parts of the body, sweat was obtained by a special procedure, the technique of which is described, from the lower third of the legs and from the feet of eight patients; it was inoculated into a 4 per cent. maltose-agar medium. In every case fungus growths were observed within a fortnight; these were studied microscopically on slides and in hanging-drop preparations. Pathogenic fungi belonging to the Kaufmann-Wolf group, and growing rapidly and abundantly, were obtained in five cases. The authors regard perspiration as being probably as important a single factor as any other in the epidemiology of ringworm infection; they expect that further similar studies will show that fungi occur in the skin of the feet of most people. Besides the fungi bacteria, *Aspergillus niger* and yeastlike organisms were also present. Microscopical studies of hanging-drop preparations showed abundant slender mycelia and numerous ectospores; in older colonies the formation of chlamydospores was common.

332 Mycosis and Pulmonary Tuberculosis

A. Barbero (*Rev. Españ. de Tuberculosis*, June, 1931, p. 253), who records two illustrative cases in patients aged 21 and 28, states that the association of mycosis with pulmonary tuberculosis has been known since 1833, when R. Owen found a fungus in a tuberculous cavity. Special attention was later devoted to the subject by Artault in 1898, Sallet in his Bordeaux thesis in 1922, Redaelli in 1925, and Braunstein in his Paris thesis in 1927. Barbero made a mycological examination of the sputum and saliva in fifty-four cases of pulmonary tuberculosis, using Sabouraud's medium, and found that 33, or 61 per cent., were positive, and 21, or 39 per cent., were negative, ninety-three different species of fungi being obtained. The fungi were more frequent in the sputum (43 per cent.) than in the saliva (21 per cent.), in which the forms most frequently found were yeasts. Barbero is of opinion that the mycotic association exercises an unfavourable influence on the course of pulmonary tuberculosis.

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopoeia, and is described as carminative, anti-spasmodic; and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 236 years.

HOW TO BECOME AN EXPERT LINGUIST

Remarkable Success of New Pelman Method of Learning French, Italian, Spanish, and German.

A REMARKABLE success has been achieved by the famous Pelman Institute with its new system of teaching languages without using English.

People who have failed to learn languages by any other method are writing to say that the new Pelman plan has enabled them to master all those difficulties which formerly prevented them from "getting on" with French, Italian, German, or Spanish.

Indeed, the success of this new method is so great that it almost seems as though it will remove the long-standing reproach that the British people "cannot learn foreign languages."

Here are a few examples of the letters now being received daily by the Languages Department of the Pelman Institute:—

"I think your (French) Course is the best method I have ever seen." (C. 272.)

"I have only been learning German for five months; now I can not only read it but also speak it well." (G.M. 14.)

"I have found your system of teaching Italian so excellent that I am recommending it to people here." (I.C. 104.)

"I have learnt more French during the last three months than I have learnt during some four or five years' teaching on old-fashioned lines at school." (S. 352.)

"I think your German Course excellent—your method of language-teaching is quite the best I have come across." (G.F. 103.)

"This is the easiest and quickest way of learning languages. In eight months I have learnt as much Spanish as I learnt French in eight years at school." (S.K. 119.)

"My progress in the French Course has been most satisfactory. I cannot speak too highly of your excellent and fascinating method." (B. 195.)

"I was able to pass London Matriculation (in Spanish) last June with minimum labour and no drudgery, although I was always reckoned a 'dud' at languages." (S.B. 373.)

"I have obtained a remunerative post in the City solely on the merits of my Italian. I was absolutely ignorant of the language before I began your Course eight months ago." (I.F. 121.)

"I have made a good deal of progress with the French and found the 'Guide to Pronunciation' particularly useful." (M. 198.)

"Regarding the (Spanish) Course, I must say that I find the method perfection, and the learning of a language in this way is a pleasure. It is simple and thorough." (S.F. 109.)

"I enclose my last work-sheet and at the same time wish to say how thoroughly I have enjoyed the whole (German) Course. I feel that the system is a splendid one and on the only sensible lines." (G.H. 214.)

"I find the (French) Course most interesting and easy to follow." (E. 245.)

"The Pelman method of learning languages is, in my opinion, the only way consistent with ease and accuracy of diction." (M. 344.)

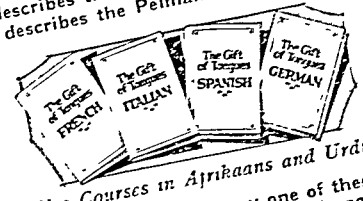
"In three months I have already learnt more Italian than I should have learnt in many years of study in the usual way. What astonishes me still more is that one can learn so well without using a single word of English." (I.M. 124.)

"Having arrived at the end of Part I of the German Course, I feel this an appropriate time in which to express my admiration of your methods. The Pelman method has changed the study of languages from a drudgery into a [illegible]" (G.M. 605.)

Amongst the advantages of the new method are the following:—

First. It is a "direct" method, and the direct method is now generally recognised to be the only scientific way of learning languages. It enables you to learn French in French, Spanish in Spanish, Italian in Italian, and German in German. No English is employed, and consequently there is no translation.

Second. There are no vocabularies to be learnt by heart. You learn the words you require by using them, and in such a way that they stay in your mind without effort.



Third. Grammatical difficulties are avoided. The Pelman method enables you to read, write, speak, and understand a Foreign Language without spending months studying dreary grammatical rules. You learn the grammar almost unconsciously as you go along.

WRITE FOR FREE BOOK TO-DAY.

The new Pelman method of learning French, German, Italian, and Spanish is explained in a little book entitled "The Gift of Tongues."

There are four different editions of this book—one for each language.

One describes the Pelman French Course.
Another describes the Pelman Spanish Course.
A third describes the Pelman German Course.
A fourth describes the Pelman Italian Course.

Also Courses in Afrikaans and Urdu.

You can have a free copy of any one of these by writing for it to-day to the Pelman Institute, 74, Languages House, Bloomsbury Street, London, W.C.I.

State which one of the four you want, and a copy will be sent to you by return, gratis and post free. Write or call to-day.

POST THIS APPLICATION FORM TO-DAY.

To those whose need of the best woollen underwear is imperative, the wisest word to say is Wolsey. For Wolsey underwear is soft and warm and comfortable. Scientific investigations* have proved that garments made of wool do more than any other to prevent the deposition of moisture on the skin; retain warmth better than any other material, and allow the most equable body temperature possible. And the purity and goodness of the wool from which Wolsey is made give it all these qualities which are essential to health and wellbeing.

"CEREBAN" ADHESIVE AND SELF-SUPPORTING Bandage

SPECIALLY PREPARED FOR THE TREATMENT OF SPRAINS DISLOCATIONS, CONTUSIONS, SWELLINGS, VARICOSE VEINS, VARICOSE ULCERS, etc., etc.

"CEREBAN" is a resin-impregnated Bandage, spread on extensible material, free from rubber and possessing elastic properties. When carefully applied it gives substantial and firm support. Porous, adhesive, and non-irritating. Experience has proved that "Cereban" Bandages are particularly suitable as a protective after-care treatment in the healing of Varicose Ulcers, etc.

"Cereban" offer many advantages over the old-fashioned Elastic Stockings or Plain Crepe Bandages ... leading to speedier recovery.

Salt and Son Ltd.

Salt's LIGHT METAL LIMB for Above Knee Amputation.

Made of duralumin with wooden foot, this limb, even for an adult patient, weighs only 3¾ lbs.

When fitted by us it possesses the following FIVE essentials —

COMFORT . . . is naturally the prime consideration.

LIGHTNESS . . . reduces the physical strain to a minimum.

ACTION . . . governs rapidity of movement and natural gait.

APPEARANCE . . . is maintained when made to match the fellow limb.

SIMPLICITY . . . in construction lessens cost of maintenance.

We manufacture wooden, leather, and metal limbs for ALL types of amputation, and can send expert fitters to any part of the country.

Illustrated lists sent on request.

MARMITE—A well-tried dietary corrective

For many years the Medical Profession has had ample clinical evidences of the beneficial effects of the addition of Marmite to the diet. An extract of Yeast, Marmite is probably the most palatable form in which adequate supplies of Vitamin B may be administered. Marmite has proved most helpful in combating fat intolerance, loss of weight, Marasmus and similar conditions. The patient will always welcome the introduction of Marmite because of its appetising flavour.

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness The Marmite Food Extract Co. Ltd, Walsingham House, Seething Lane, London, E.C.

Collection of Overdue Accounts

The principal object of this Society is to put money into the pockets of Medical Men—not to take it out.

What we want is the recommendations of the Profession, and the only way to get recommendations is by collecting their overdue fees—

WITHOUT OFFENCE

Your visiting card marked "B" placed in an envelope will bring our Prospectus.

Telephones: Langham 1411-1412
Secretary: N. Rutherford Watson.

FOR INTERNAL TREATMENT OF GONORRHOEA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations. There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or tolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito Urinary tract. The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt St Andrew St., W.C.2

SANTAL MIDY

TWO FUNCTIONS of ROBINSON'S "PATENT" GROATS

In infant dietetics the gradual introduction of Groats and milk at about 6 months is the most important step in educating baby to take the varied diet of later years. Groats renders the milk digestible, and its slight laxative properties counteract the constipating qualities of the milk. Robinson's "Patent" Groats and milk forms a nourishing diet with a suitable fat content, and affords an excellent source of calcium so essential to expectant and nursing mothers.

Samples and laboratory details free on request to:

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sound from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the Last B.M.A. Meeting.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: The Most Hon. the Marquess of Exeter, C.M.G., A.D.C.

Medical Superintendent: Daniel F. Rambaut, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are *suffering from incipient* mental disorders or who wish to prevent recurrent attacks of mental trouble, *temporary patients*, and certified patients of both sexes, are received for treatment. *Careful* clinical, biochemical, bacteriological, and pathological examinations. Private rooms, *with special nurses*, male or female, in the Hospital or in one of the numerous villas in the grounds of the *various branches* can be provided.

WANTAGE HOUSE.

This *is a Reception Hospital* in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It *contains* special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières *treatment, etc.* There is an Operating Theatre, a Dental Surgery, an X-ray Room, *an Ultra-violet Apparatus*, and a Department for Diathermy and High Frequency treatment. It also *contains Laboratories for* biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by *appointment*.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel: 64117. *For terms, etc., apply to the Medical Superintendent.*

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg Tel Address Bethlem, Beckenham. *Telephone* Springpark 1180—1181.

Station. Eden Park (Southern Railway)

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D
Treasurer: SIR LIONEL FALDER-PHILLIPS, Bart
Physician-Supt: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds. Applications can be considered on behalf of patients of the educated classes in a presumably curable condition. With a view to early treatment voluntary uncertified patients are admitted.

Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as voluntary boarders. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.

Every facility for special investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.

Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.

In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.

The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.

For forms and further particulars apply to the Physician Superintendent at the Hospital.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week, beginning on October 15th, 1931.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings, all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing, *medicines or vaccines, board and lodging*.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 29·5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. *Telegrams*: CASTLE, RUTHIN. *Telephone*: RUTHIN 66.

CAMBERWELL HOUSE, 33, Peckham Road, London, S.E.5.

Telegrams: "PSYCHOLIA, LONDON." FOR THE TREATMENT OF MENTAL DISORDERS. *Telephone*: RODNEY 4721—4732.

APPOINTMENTS.—Contd.

Derbyshire County Council.

WOMAN MEDICAL OFFICER.

The Derbyshire County Council require the services of a fully qualified Whole time Woman Medical Officer experienced in Ante-Natal Work, Midwifery and Children's Diseases, to hold (under the direction of the Medical Officer of Health) Consultations at the Maternity and Child Welfare Centres of the Derbyshire County Council, and (under the like direction) to perform such other duties as appertain to the office.

The salary will be £600 per annum, rising by £25 per annum to £750 per annum.

The appointment will be a designated post under the Local Government and Other Officers Superannuation Act, and the successful candidate will be required to pass a medical examination.

The appointment will be terminable by one month's notice on either side.

Applications must be sent to the undersigned, together with copies of not more than three recent testimonials, not later than Saturday, October 24th.

W. M. ASH,
County Medical Officer of Health.

New County Offices,
Derby.

St. Albans and Mid Herts HOSPITAL AND DISPENSARY, CHURCH CRESCENT, ST. ALBANS.

Applications are invited for the post of RESIDENT HOUSE SURGEON (male or female). Salary £150 per annum, with board, residence, and laundry.

Applications to be sent to the Secretary, St. Albans and Mid Herts Hospital, No. 38, St. Peter's Street, St. Albans.

October, 1931.

County Council of Middlesex.

REDHILL COUNTY HOSPITAL EDGWARE.

RESIDENT ASSISTANT MEDICAL OFFICER

The County Council invite applications for the post of Resident Assistant Medical Officer at the Redhill County Hospital Edgware.

Candidates must be registered Medical Practitioners who have held resident appointments in a General Hospital. The officer appointed will work under the control of the Medical Superintendent and will devote himself to the hospital duties.

Salary is at the rate of £400 per annum rising by annual increments of £50 to £600 per annum together with board lodging and laundry.

The successful candidate will be required to pass such medical examination as the County Council may direct and unless subject to the Poor Law Officers Superannuation Act 1896 to contribute to the County Councils Superannuation Fund. The appointment will be held during the pleasure of the Council and subject to one month's notice on either side.

Applicants stating (1) age (2) qualifications and (3) previous experience together with copies of not more than three recent testimonials must be received by the undersigned not later than October 24th.

No special application forms are provided. Envelopes must be endorsed Resident Assistant Medical Officer.

Canvassing directly or indirectly will be a disqualification.

NB—Redhill Hospital is a modern General Hospital with accommodation for some 200 acute cases and a similar number of patients at the adjoining Redhill Institution suffering from chronic disease are under the care of the Medical Staff of the Hospital.

LONDON

HOSPITAL SERVICE.

The LONDON COUNTY COUNCIL invites applications for appointment to the following posts:

The persons appointed will be required to carry out such duties as may be agreed by the Medical Superintendents and Committees in charge under the control of the Council. The successful candidates will be required to live in the Hospital. There is no accommodation for married officers.

ASSISTANT MEDICAL OFFICERS

Salary £330 a year rising by annual increments of £25 to £425 together with board, lodging and washing. Candidates must be duly qualified Medical Practitioners of at least one year's standing. Experience in a recognized appointment in a General Hospital is desirable.

(1) ST. LUKE'S HOSPITAL, Lower Road (for acute mental cases) (210 beds). For pulmonary and female cases. Light treatment and X-ray facilities. Experience in the treatment of mental disorders is desirable.

(2) HIGH WOOD HOSPITAL FOR CHILDREN, Brentwood Essex (370 beds). Experience in the treatment of tuberculosis is desirable.

(3) DOWNS HOSPITAL FOR CHILDREN, Sutton Surrey (260 beds). Experience in administration of anaesthetics is essential.

(4) GROVE PARK HOSPITAL, Lee S.E.12 (322 beds). Experience in the treatment of pulmonary tuberculosis is desirable.

HOUSE PHYSICIANS

Salary £80 a year together with board, lodging and washing. Appointment is for six months only in the first instance but may be extended for a further period of six months up to a maximum of two years provided that not more than 12 months are spent at one hospital. Candidates must be qualified Medical Practitioners without necessarily having had previous hospital experience.

KING GEORGE V SANATORIUM Godalming, Surrey (Two appointments) (232 beds). For early cases of pulmonary tuberculosis in women.

Forms of application may be obtained (stamped addressed foolscap envelope necessary) from the Medical Officer of Health (Staff Division) The County Hall Westminster Bridge S.E.1 and must be returned by October 30th. Candidates should specify the position or positions for which they desire to apply. Canvassing disqualifies. Inquiries for further details as to the nature and scope of the duties should be addressed to the Medical Superintendents at the respective Hospital.

MONTAGU H. COX,
Clerk of the London County Council.

City of Birmingham.

PUBLIC HEALTH COMMITTEE.

LITTLE BROMWICH ISOLATION HOSPITAL. WITTON SMALL-POX HOSPITAL.

MEDICAL SUPERINTENDENT OF INFECTIOUS DISEASES HOSPITALS.

Applications are invited from fully qualified registered Medical Practitioners for the above whole-time appointment.

The Little Bromwich Hospital has accommodation for 466 patients mainly scarlet fever and diphtheria cases while the Witton Small-pox Hospital can accommodate 100 patients.

All communications to be addressed to the Branch Manager BRITISH MEDICAL BUREAU, 33, CROSS ST., MANCHESTER.

Before the Operation and After

In preparation for the operation  one tablespoonful of Agarol on retiring  in place of the usual castor oil, will insure against gastric upset.  Again, a few days later  when the patient begins to take nourishment  Agarol in half doses  is the logical eliminant because it stimulates peristalsis  gently without griping or pain.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Agarol Brand Compound is palatable without artificial flavouring and easy to take. The usual dose in chronic constipation is a tablespoonful, reduced as improvement takes place.

A supply gladly sent for trial.

AGAROL BRAND COMPOUND *for Constipation*

FRANCIS NEWBERY & SONS, LTD., 31-33, Banner Street, London, E.C.1.

STANIFORM

Regd BRAND Trade Mark

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns scalds, etc.

DUSTING POWDER
For application where a greasy substance is counter indicated

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis

LOTION
A panacea for Mosquito and other insect bites Most effective for all purposes where Tr Iodine is employed Does not stain the skin and there is no sting

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men

"After using 'Staniform' Ointment in cases of Impetigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment Also helped on the lip quickly disappeared after application of 'Staniform Ointment"

"Festering wound on left heel—when first seen was about the size of a shilling with a good deal of pus Foot much swollen—dressed with Staniform Ointment —healed splendidly in four days"

Similar testimony has been received from a large number of medical men when Staniform has been used for the treatment of Burns Wounds and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited great restorative properties Combining the well known therapeutic properties of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

Supreme in purity

'Wellcome' Brand Insulin is supreme in purity and therapeutic activity. It retains its efficiency to an exceptional degree

It contains the minute amount of antiseptic considered by leading bacteriologists to be essential in insulin to inhibit the growth of micro-organisms which may be accidentally introduced

This precaution is particularly necessary as in many cases patients make the injections themselves

TRADE MARK 'WELLCOME' BRAND

Syrup Cocillana Comp.

PARKE DAVIS & CO.

THIS thoroughly efficient soothing and expectorant combination is particularly adapted for the treatment of acute bronchitis; also of chronic bronchitis when secretion is scanty and cough excessive. In the inter-paroxysmal stages of asthma, its administration is useful to allay dyspnœa. It does not arrest the secretions or cause constipation. It is most agreeable in flavour and attractive in appearance.

Each fluid drachm contains:—

Tincture of Cocillana	5 mins.	Fluid Ext. of Squill	1/4 min.
Tincture of Euphorbia Pilulifera	15 mins.	Fluid Ext. of Senega	1 4 min.
Syrup of Wild Lettuce	15 mins	Tartarated Antimony	1 1⁸⁴ gr.
Cascarin (P, D & Co)	1 gr	Menthol	1 100 gr.
Ethylmorphine Hydrochloride	1,32 gr.		

Syrup Cocillana Compound (P, D & Co) is supplied in bottles of 4, 8, 16 and 80 fl ounces

Parke, Davis & Co., 50 Beak Street, London, W. 1.

Laboratories: Hounslow, Nr. London .·. Inc U.S.A., Liability Ltd.

ANTIPHLOGISTINE

BRAND DRESSING

in Gynæcological Conditions

Endocervicitis

There is no gynæcological condition which is seen more frequently by doctors in all types of practice, and which is more difficult to treat satisfactorily, than chronic endocervicitis.

A most excellent remedial method for this condition is the use of hot tampons of Antiphlogistine Brand Dressing. These are formed of a cup-shaped lump of the dressing enclosed in a single layer of gauze, heated as hot as can be borne, and pressed and moulded right up against the vaginal vault, to be removed after six hours.

The relaxant, depletant and analgesic properties of Antiphlogistine Dressing have made it a standard topical application for inflammatory and congestive conditions.

ENGINEERING PROBLEMS IN ABDOMINAL DISPLACEMENTS SOLVED BY SURGICAL BELTS

The medical profession is beginning to realise that when it is a matter of internal displacement, abdominal disorders will not yield to stimulation or lubrication from within. These methods ignore the mechanical problems which would be the first consideration of an engineer called upon to conserve the function and structure of a coiled, mobile and valved tubing such as the alimentary system. The solving of these problems is the first consideration in the construction of Domen Surgical Belts.

These Belts correct and prevent mechanical faults in the engineering system of the abdomen by counteracting with upward support the downward pull of gravitation. And to do this Domen Belts rest upon the only anatomically legitimate foundation—the bony pelvis. Domen Belts are designed for specific complaints. They fit well and comfortably. They leave the patient free and unembarrassed. Your card or a telephoned request will bring you full particulars.

DOMEN SURGICAL BELTS

DOMEN BELT CO. LTD., 26, SLOANE STREET, LONDON, S.W.1. Telephone: Sloane 3524

An urgent call

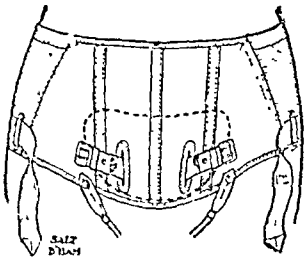
It may not be as urgent as the patient thinks, but however that may be it is in the interests of all concerned that you get there quickly. Night or day this applies, hence the reliability of the car you drive is an all-important consideration.

"Plus-ultra" Two-Seater Coupé

will get you there just every time and additionally provides ample and convenient accommodation for the impedimenta you must carry with you. For instance, in the dash there are two Yale-locked cubby holes, and built into the rear of the body a large and commodious locker, also yale-locked, accessible from either interior or exterior. It is a handsome car, possessing all the Riley individuality, both in appearance and performance—has a large dickey seat, drop head and Triplex opening screen and windows. You can see it at

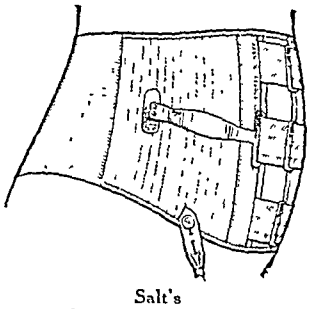
the "Blue Spot" at Olympia

(Stand 106)



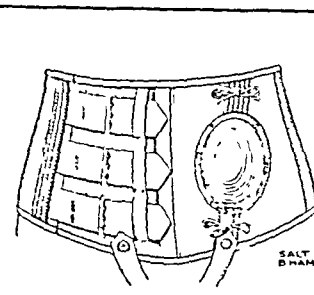
or we will gladly arrange a demonstration on receipt of your request.

RILEY (COVENTRY) LIMITED, COVENTRY, & 42, Nth. Audley St., LONDON, W.1



SURGICAL SERVICE
SALTAIR

"SALTAIR SURGICAL SERVICE"



Competence

Front View.
Salt's
Patent Gastroptosis Belt.

Salt's
Patent Kidney Belt.

Salt's
Patent Colostomy Belt.

THE competence of Saltair Surgical Service has been engendered by 138 years' constant co-operation with the Medical Profession.

During that period we have produced numerous types of Appliances in close collaboration with eminent Medical Men.

We have supplied thousands of specially made Appliances to Doctors' own measurements.

We employ only competent fitters and craftsmen—every Salt Appliance is produced at a price acceptable to the means of even the poorest patient.

Birmingham:
Midland 5455.

London:
Museum 3845.

SALT AND SON LTD.

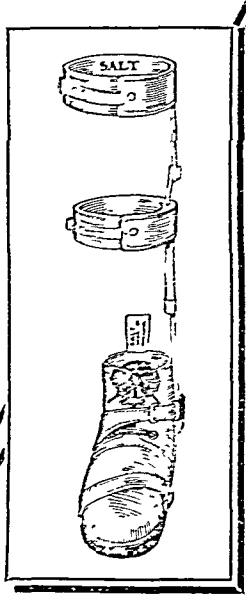
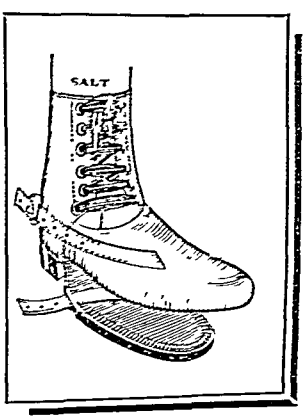
COPYRIGHT

SALTAIR SURGICAL SERVICE



creates Confidence



SINCE 1793 the Saltair principle has remained unaltered.

That the qualified Medical Man represents THE authority for prescribing the type of Appliance for each case.

That such Appliance be specially constructed to this prescription.

To this, Saltair Service . . . sure in its knowledge and experience of interpreting Medical requirements . . . adds its famous guarantee, that in the case of the Appliance proving unsuitable, or the patient declining to wear it, it can be returned, without any obligation to the Medical Man, within 14 days from date of supply.

London Consulting Rooms

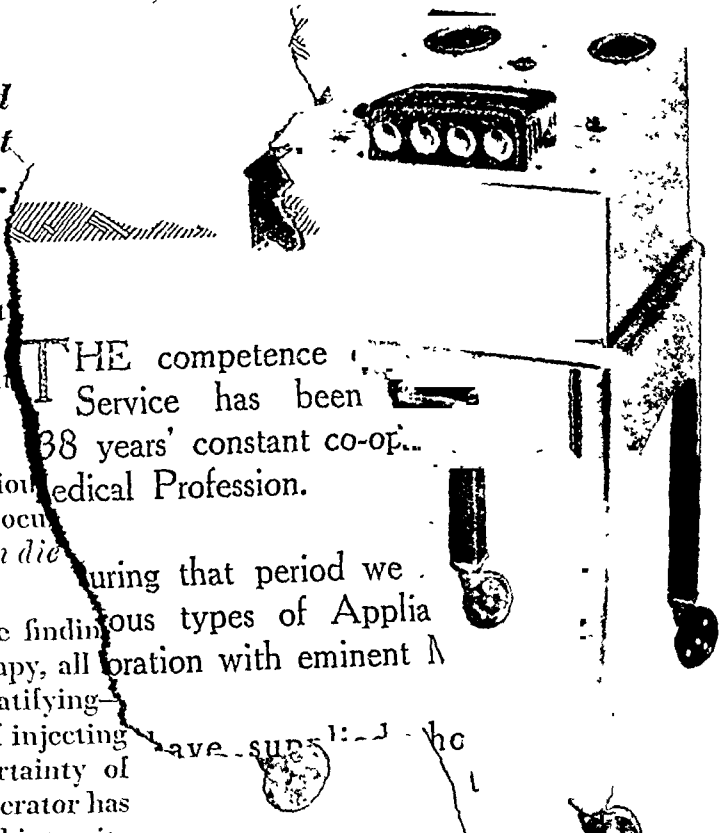
ESTABLISHED 1793.

They let their malarial strain *die out!*

Diathermy replaces antiquated methods of paresis treatment in English mental institution.



LAST spring we had the pleasure of cooperat
a prominent Midlands institution with a
assisting in the inauguration of a clinic for trea
paresis by pyretotherapy.

Their results have been so much more efficacio
by any former methods—including malarial inocu
—that *they have now let their malarial strain die*

This we believe conclusive confirmation of the findin
made by other investigators of this form of therapy, all
whom agree that the results obtained are very gratifying—
offering definite advantages over any method of injecting
pathogenic organisms and the attendant uncertainty of
their secondary effects. With diathermy, the operator has
accurate control of the frequency, duration, and intensity
of the fever.

For this important work Victor apparatus has been selected
after an extensive investigation to determine what repre-
sented the most scientifically designed equipment best
suited to the exacting requirements. It is another instance
serving to prove that critical comparison with all makes
of electro-medical apparatus results favourably to Victor.
Obviously, for *Victor* apparatus is scientifically correct,
embodying the experience of pioneers in the industry plus
the fruits of research in the world's finest laboratory—in
short, facilities which are unapproached by any other
manufacturer.

Upon request we will gladly send reprints of papers on
the production of artificial fever with diathermy, together
with description of the necessary Victor apparatus.

THE competence
Service has been
38 years' constant co-op
edical Profession.

uring that period we
ous types of Applia
oration with eminent M

ave sup
hc

The Victor Super-Power Diathermy Apparatus Designed for Producing Therapeutic Fever

Capable of raising the body temperature to the desired degree, under absolute control of the operator at all times.

Will give as much current as any patient can tolerate through the chest and abdomen with the largest size electrodes used thus far in this work.

With a control system which permits the selection of both frequency and voltage, the quality of current desired is quickly available.

This refinement of control applies throughout the range of the machine, from the low current values up to and including the high. Thus the outfit serves every purpose of diathermy known to medical science up to the present.

It is shock-proof! The control panel is so designed that there are no exposed parts to endanger the operator or patient.

Light treatment in two forms from one unit——

The Duo-Therapy Unit

THE Hanovia Duo-Therapy Model gives in one unit powerful modern lamps for both ultra-violet and luminous heat (infra-red) treatment. It embodies:

The *standard Alpine Sun* in its new improved form of increased intensity. Standard of the world for ultra-violet treatment.

The *Sollux Lamp* (1,000 watt unit) for luminous heat treatment in its general or local form.

Each form of treatment separately administered and independently controlled.

Hanovia apparatus for light therapy—specialised product of twenty-five years experience—is supplied through electro-medical dealers at inclusive prices, covering delivery and service in Great Britain.

This and the other new British Hanovia models offer to the profession an even higher standard of service and value in Actinotherapy than before. To all professional users of British Hanovia lamps a free copy of the bulletin, "The Quartz Lamp," is sent regularly. See that you receive your copy.

BRITISH HANOVIA QUARTZ LAMP CO. LTD. SLOUGH, BUCKS (Dept. 9)

Please send literature on light therapy and details of your new models.

THE CONCENSUS OF SCIENTIFIC OPINION
SOLIDLY IN FAVOUR OF
ALUMINIUM WARE

BRITISH

"The Lancet," 3/1/31.
Some seventeen years ago we ourselves made experiments showing that 'aluminium, as it is now made by reputable manufacturers, is a suitable material for cooking vessels,' and again quite lately we published analytical information leading to the conclusion that 'even if small quantities are conveyed to the water or food, these are without influence on the health of the individual.'" (See also "The Lancet," 4/1/13 and 15/12/28.)

AMERICAN

American Medical Association, Bureau of Investigation.
"There is not the slightest scientific evidence to show that the use of aluminium cooking utensils is in any way harmful to health, or that it has any material effect on foods or water used in such utensils."

GERMAN

"Prof. K. B. Lehmann (Director of the Institute of Hygiene) of Würzburg University, has lately examined the alleged dangers of aluminium vessels. . . . Aluminium, he says, has no action on the liver or the vessels. Natural food contains on average daily quantity of 20-25 mg., and if aluminium vessels are used, about 40-60 mg. In America, where the use of baking powder with aluminium is allowed, about 250 mg. are daily swallowed, but the quantity is too small to do any harm to the consumers." (Vide "The Lancet," 3/1/31.)

A résumé of published evidence by British, American, and Continental medical authorities will be sent gratis on request.

ALUMINIUM INTELLIGENCE BUREAU, Adelaide House, London, E.C.4.

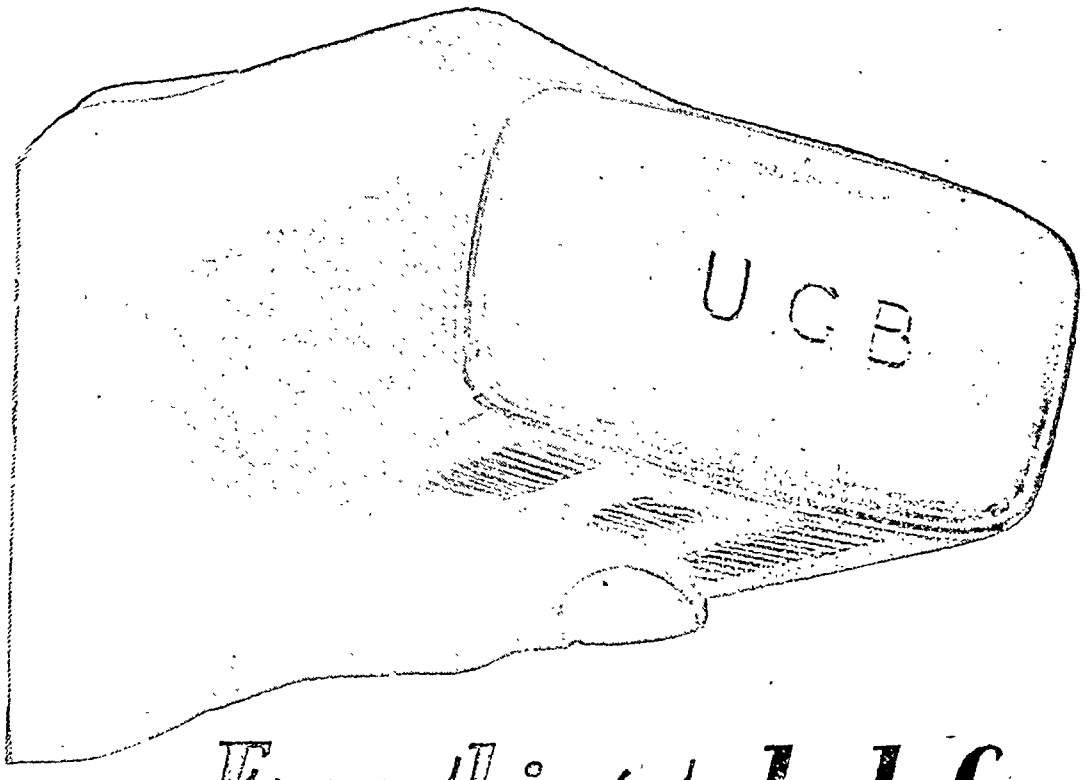
"Kodak" X-Ray Reduction Camera



A simple and solidly built camera. Reduces negatives of any size up to 17 x 14 ins.

Suitable for making bromide prints or transparencies of $6\frac{1}{2}$ x $4\frac{3}{4}$ size or smaller, and lantern slides.

An automatic focussing scale makes the "Kodak" Reduction Camera exceedingly simple to operate.

Kodak Limited, (Medical Dept.)
Kodak House, Kingsway,
London, W.C 2.

Everything to look for on a Bottle..

IMITATION may be the sincerest form of flattery, but the extent to which the U.G.B. Medical Bottle is imitated in inferior quality is far from gratifying.

Designed some ten years ago as an ideal dispensing bottle, it is now the standard for this purpose. The consistently high quality, accurate capacity and attractive appearance, places the U.G.B. Medical in a class by itself.

The success of this bottle has been greatly enhanced by the introduction of the "WASHED & STERILIZED READY-TO-USE BOTTLE" packed in non-returnable Dustproof Solid Fibre Cartons—supplied either for Corks or complete with Rustless White Enamelled Screw Caps.

Obtainable from all leading Wholesalers.

HORLICK'S *for*
The EXPECTANT MOTHER

When added to the diet of expectant mothers *Horlick's Malted Milk*:—

1. *Provides extra nourishment* in an easily digested and assimilated form. Horlick's causes no digestive disturbances.

2. *Helps the elimination of waste products.* Constipation is frequently a troublesome feature of pregnancy. Horlick's promotes good bowel habits, and prevents constipation. As a food-drink it helps elimination by the kidneys.

3. *Prevents and relieves morning sickness.* The easily assimilated carbohydrate content of Horlick's Malted Milk counteracts the mild toxaemia, which causes many cases of morning sickness.

4. *Promotes sleep*—sleeplessness frequently complicates pregnancy, and adversely affects its course by increasing both worry and fatigue. Horlick's, by promoting sound sleep, places the patient in a favourable position to counteract these adverse influences.

Horlick's Malted Milk Co., Ltd., Slough, Bucks.

The 'Allenburys' Kaolin with Paraffin

A Detoxicating Lubricant

The "Allenburys" Kaolin with Paraffin contains a combination of two already well known preparations —20 per cent. of "Osmo" Kaolin with 33⅓ per cent. of "Chrismol" Liquid Paraffin. These two constituents are so finely diffused that they form an emulsion which ensures the highest possible therapeutic effects.

The "Allenburys" Kaolin with Paraffin is indicated in all conditions in which elimination of intestinal toxins and protection of the intestinal mucosa are necessary, e.g. in chronic constipation, intestinal toxæmia, colitis, summer diarrhœa, food poisoning, cholera, etc.

In bottles: 8 oz. and 16 oz. for prescribing
80 oz. for dispensing.

Literature and clinical trial samples will be sent post free on application.

Roboleine

THE FOOD THAT BUILDS THE BODY

A POWERFUL reconstructive food that can be administered in all conditions, even those in which ordinary concentrated feeding and tonics are not supported, must fill an important place in therapeutics. Such a product is found in "Roboleine," which has been before the Medical Profession for nearly 25 years.

Bone-Marrow in Anaemia from Haemorrhage.

W. Borchardt (Deut. med. Woch., March 28th, 1930, p. 521) records the results of his experiments on young dogs in which anaemia had been artificially produced by the removal of about half their blood. In the first series some of the animals were fed with rib marrow, others with marrow from the long bones. Control animals received a corresponding amount of either fat or of liver extract. The basal diet in each case contained a sufficiency of iron (5 mg. per cent.). Only the animals receiving the red rib marrow showed a definite increase in weight, and their haemoglobin formation was more rapid than that of the others. In the next series the experiment was repeated, but the iron content of the diet was reduced to 1·4 mg. per cent. The result was similar but more striking, the dogs receiving the rib-marrow regaining their haemoglobin far more quickly than the others.

—*Vide* B.M.J., May 3rd, 1930.

"ROBOLEINE" contains the Marrow from the long bones, the RED MARROW OR JUICE FROM RIB BONES OF OXEN, together with Egg Yolk and a specially prepared Extract of Malt.

This is the original formula, and it may be of interest to note how closely it conformed to the latest requirements of modern research. This formula, however, has been developed in the light of clinical experience, and the vitamin content has been reinforced by the addition of our "Vitad," which is the unsaponifiable fraction of Cod Liver Oil.

ROBOLEINE may be taken by itself, or mixed with water, milk, porridge, or tea, and spread on dry biscuit forms a nourishing and stimulating "snack" lunch for children or adults.

INDICATIONS:—Rickets, Phthisis, Anaemia, Leukemia, Lymphadenoma, etc., and in those cases in which a debilitated stomach has rendered convalescence slow and difficult.

TESTING SAMPLE.

In Infancy

WHETHER the child be breast fed or bottle-fed, constipation is often a trouble-some feature. Castor oil and other purgatives, or aperients, while securing a prompt action of the bowels, possess certain definite disadvantages with which the practitioner is fully acquainted

"Cristolax," a combination of 50% of the purest medicinal paraffin of correct viscosity and 50% "Wander" Dry Malt Extract, is of special value for infants, particularly for those who are artificially fed.

One teaspoonful dissolved in three feeds a day, no matter whether they consist of milk or infants' food, renders the feeds more easily digestible, prevents the formation of hard indigestible clots, and keeps the bowels in a regular and sweet condition.

"Cristolax" is also an admirable preparation for the nursing mother, both during gestation and the lying-in period. Its use ensures regular and adequate defecation without griping, straining, or harmful effect upon the child.

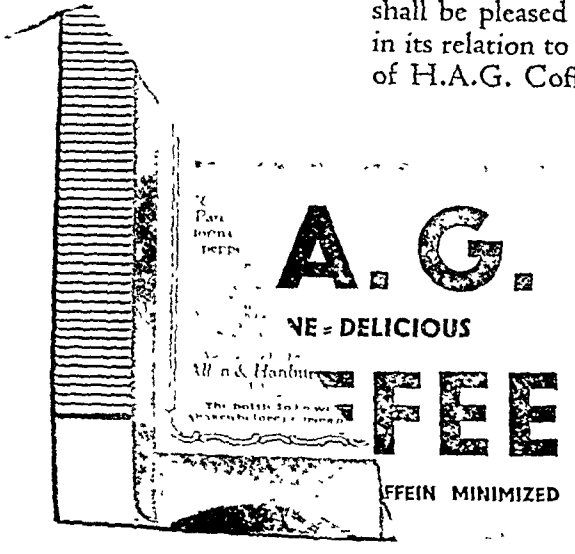
MARCUS AURELIUS AS AN AROAL BROTHER

with the caffein problem in mind—make the Night-Test

Do you have misgivings when you forbid a patient coffee? Do you doubt the patient's ability to say "No" to coffee's tempting fragrance?



With this problem in mind, send the coupon below for a free vacuum-packed tin of H.A.G. Coffee—genuine, delicious coffee, with the effects of caffein minimized. When it arrives, make the night-test—drink your first cup of H.A.G. Coffee at night. Next morning you'll know, from your own experience, that any patient can drink H.A.G. Coffee without danger of caffein effect. More than that—you'll know that the rich, satisfying flavour of H.A.G. Coffee will shield the patient from the temptation to drink caffein-containing coffee.

Real coffee—delicious coffee!

H.A.G. Coffee is real coffee—a superior blend of the choicest Central and South American coffees. The decaffeination process takes place *before* the coffee beans are roasted. This leaves intact all the mellow flavour and fragrance that make coffee "the beloved beverage." Coffee experts recognize that no other blend is finer.

H.A.G. Coffee is under the Independent Control of The Institute of Hygiene and British Analytical Control.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Coffee drinking in its relation to Health," a more complete discussion of H.A.G. Coffee. Send the coupon now.

H.A.G. COFFEE COMPANY,
40 Theobald's Road, W.C.1

Please send me free of charge a liberal sample of H.A.G. Coffee—also some literature upon the action of Caffein.

'Just as Vitamin D holds the key to the formation of teeth and bones so Vitamin A controls the structure of some epithelial tissues. . . .'

(*Report of Hastings Lecture, Supplement, B.M.J., March 21st, 1931, p. 85*)

RADIOSTOL
Standardised Vitamin D

THE recent report on '*The influence of diet on caries in children's teeth*' by the Medical Research Council demonstrates that the onset and spread of dental caries in children can be controlled by the addition of Radiostol to the normal diet. The report states further that '***the successful research . . . in this field points to immediate and widespread measures of preventive control***'.

Radiostol Solution for such preventive measures ***—exactly identical with that used in the investigation***—is available to any physician from the principal pharmacists.

RADIOSTOLEUM
Standardised Vitamins A & D

In a recent investigation on the anti-infective action of Vitamin A (B.M.J., Oct. 3rd, 1931, 595) Radiostoleum was administered to 275 women during the later weeks of pregnancy whilst another 275 were kept as controls; it was found that only 1·1 per cent of the treated cases as against 4·7 per cent of the controls developed infection (B.M.A. standard of morbidity), ***thus showing less than one-fourth the susceptibility to infection when Radiostoleum is administered.***
Similar remarkable results of a smaller-scale experiment with Radiostoleum were reported previously (B.M.J., June 15th, 1929, 984).

AVOLEUM
Standardised Vitamin A

The anti-infective Vitamin A is available also through the medium of Avoleum—a highly-concentrated standardised liquid preparation of Vitamin A without the admixture of Vitamin D. Whilst Radiostoleum is recommended for administration to children and to pregnant and lactating women, Avoleum is more suitable for elderly patients and for cases in which the calcifying Vitamin D is contra-indicated.

Collosol "F.C.V.D."

FOR BLOOD REGENERATION, RECTIFYING CALCIUM DEFICIENCY AND GROWTH PROMOTION

Facsimile of label

In recent years the work of Hart, Steenbock, McHargue, Elvehjem, and others, suggests that the beneficial effect of iron therapy is largely due to the presence of a minute copper content present as an impurity.

Collosol "F.C.V.D." comprises colloidal iron activated by a small quantity of copper. Further, as calcium deficiency is frequently associated with anaemias and debility it has been considered advisable to make use of the well-established function of Vitamin D in calcium absorption. This accessory food factor has been added in the form of irradiated ergosterol combined in the medium of pure malt extract (Vitamin B) with orange juice (Vitamin C).

LIVER THERAPY PER OS

HEPATEX is the most efficacious Liver Extract for administration per os. It contains the principle active in pernicious anaemia and in addition the full Vitamin B complex. Hepatex is a proved remedy not only for pernicious anaemia, but is also of considerable value in other anaemic conditions. It is so concentrated that one fluid drachm is equivalent to two ounces of fresh liver.

Issued in 4-oz. bottles.

HEPATEX WITH IRON has been introduced for the treatment of those cases of severe secondary anaemia where a combination of liver and iron is indicated. The special form of iron used is greatly superior to standard iron preparations as regards assimilation and absence of gastro-intestinal disturbances. A dosage of one or two fluid drachms a day gives a most satisfactory response.

Issued in 2-oz. bottles.

LIVER THERAPY BY INJECTION

HEPATEX P.A.F. has been introduced by us for the injection treatment of those cases of pernicious anaemia where speed of action is essential. It is presented as a highly concentrated, non-toxic solution, which on injection produces an immediate reticulocyte response. Cases of pernicious anaemia with red cell counts as low as 600,000 have responded satisfactorily, and the need for blood transfusion is entirely obviated. It is also useful where liver administered orally is not tolerated. The dose varies from 5 c.c.'s intravenously per day to 5 c.c.'s intramuscularly per week, according to the clinical condition.

Issued in 5 c.c. ampoules.

TO THE MEDICAL PROFESSION

T.C.P.

B_3 COLLOIDAL EMULSION

For the treatment of Enteritis, Gastro-Enteritis, Colitis, Hyperchlorhydria, Constipation, Dysentery, Rheumatism, Arterio-Sclerosis, Hypertension.

FORMULA.

Trichlorophenylmethyliodosalicyl	1.00%
Tribromoacetyliodoorthooxybenzoic Ac.	2.00%
T.C.P. Bismuthate	1.50%
Colloidal Aluminium Silicate	2.00%
Glycerine	3.00%
Distilled Water	90.50%
	100.00%

THE CHEMICAL REACTIONS WHICH TAKE PLACE IN THE INTESTINAL TRACT AFTER INGESTION OF T.C.P. B3 COLLOIDAL EMULSION

T.C.P. B3 Colloidal Emulsion is acid and passes unimpaired through the acid medium of the stomach. But immediately it reaches the alkaline region of the duodenum, chemical reaction occurs and the chlorine content is liberated.

Chlorine, thus free, attacks with avidity the amino-acid groups and the bacterial proteins and renders them innocuous.

This leaves phenyl-iodo-salicylic acid which in the same alkaline medium liberates iodine.

The affinity of free iodine for hydrogen liberates oxygen which by oxidation acts on the bacterial toxins and renders them also innocuous.

Phenyl-salicylate (or Salol) is left, which is well known to have very beneficial effect in all forms of Colitis.

These halogens—chlorine and iodine—together with the last product, phenyl-salicylate, are liberated in the body in a nascent state and in a most assimilable form ; they are moreover liberated in the actual position in the bowel where their therapeutic action is required.

The bromine element in the compound is also liberated and imparts a comforting and sedative effect on the nervous system.

MEDICAL REPORTS

——, M.B.Lond., sometime **Deputy Commissioner of Medical Services, London Region, Ministry of Pensions,** reports :—

"In my experience of over two years T.C.P. B3 Colloidal Emulsion has been most efficacious in many cases which in the past have failed to respond to treatment by the ordinary alkaline medication."

Dr. ——, Bengal, reports :—

"By using your T.C.P. B3 Colloidal Emulsion in a case of long continued Dysentery I have got a very brilliant satisfactory result. I think this is the and only medicine that has been discovered for dysentery."

MEDICAL REPORTS

Some experience of the Medical Profession from amongst numerous reports emphasising the value of T.C.P.

Late Director-General, Medical Department, Admiralty, London, reports :—

"T.C.P., I have to inform you that a trial has been made of the preparation with results which were quite satisfactory."

——, M.R.C.S., L.R.C.P. Lond., late Medical Officer of Health, reports :—

"I have continued the use of T.C.P. . . . on a variety of cases. I do not wish to appear too enthusiastic, but I cannot tell you how very satisfactory it has been without appearing to exaggerate."

——, M.B. Lond., sometime Deputy Commissioner of Medical Services, London Region, Ministry of Pensions, reports.—

"T.C.P. . . . the value of which has been demonstrated and appreciated by many surgeons who have used it. The point to be emphasised is that here is an efficient antiseptic, which can have no toxic, corrosive or irritating effect on any tissue, and can also be given internally with confidence as an ideal gastro-intestinal antiseptic."

Nutritional anaemia in infancy

IT has recently been shown that breast milk does not contain an adequate amount of iron and that from the early days of infancy it is necessary to supply iron to the organism, if healthy development of the child is to be attained.

The organic iron in Virol from Glycerine Extract of Red Bone Marrow and from yolk of eggs is absorbed with ease.

The vitamin-containing Fats are very finely emulsified; they are, therefore, easily digested by the most sensitive alimentary tract at all ages, including earliest infancy.

All experience goes to show that Virol is a food of marked value in a great variety of conditions in which adequate nutrition by ordinary means is not easy to secure.

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
2 c.c. size: Boxes of 10 ampoules.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

Observations ON RESUSCITATION FROM ASPHYXIA AND PREVENTION AND TREATMENT OF SECONDARY PNEUMONIA BY INHALATION OF CO_2

BY

YANDELL HENDERSON, PH.D.

PROFESSOR OF APPLIED PHYSIOLOGY, YALE UNIVERSITY

(From the Laboratory of Applied Physiology, Sheffield Scientific School, Yale University)

The modern art of resuscitation takes its origin from the introduction about twenty-five years ago, of the prone-pressure method of artificial respiration devised by Sir Edward Sharpey-Schafer. In America, where it was early adopted, the number of persons trained to administer it is estimated at fourteen millions. In the saving of life its efficiency far surpasses that of any other procedure or apparatus. It has almost entirely replaced in America the quite ineffective and sometimes harmful, subcutaneous and intracardiac injections of adrenalin and other drugs by physicians ignorant of sound methods of resuscitation. Yet unfortunately the depression of vitality following many accidents, immersion, asphyxia, and anaesthesia still causes subsequent deaths among those temporarily revived.

It is not enough to resuscitate a man from drowning or from asphyxia or other accident, if he is to die a few days later from a secondary pneumonia. The pneumonia should also be prevented, and this is now possible by the method which I shall describe.

The subject to be discussed in this paper includes, therefore, not only resuscitation from carbon monoxide asphyxia and from many kinds of gas poisoning, resuscitation from drowning, and the resuscitation of babies that do not breathe of themselves at birth, but also other even more important applications of the physiology of respiration such as the elimination of the anaesthetic and the restoration of vitality in patients who, without this treatment after major surgical operations, may lie for hours in a state of functional depression. But most important of all is the recent discovery that in a wide variety of conditions inhalation of carbon dioxide is a highly effective preventive—indeed, it is essentially the specific preventive of the condition in the lungs from which it is probable that all secondary pneumonias develop.

Twenty-five years ago Haldane, Priestley, and Douglas in England began their epoch-making work on the part that carbon dioxide plays in respiration. Simultaneously in America I developed some other aspects of the regulation of vital functions by the carbon dioxide produced in the body. These observations led me to realize the possibility of using inhalation of carbon dioxide in the prevention and treatment of functional depressions after surgical operations and in acute disease.

The results have verified the almost inspired dictum of the Swiss physiologist Miescher, who, forty years ago, in a celebrated review of all previous investigations on respiration, remarked: "Over the oxygen supply of the body carbon dioxide spreads its protecting wings."

Eminent surgeons and physicians in public addresses sometimes complain that physiologists devote themselves too exclusively to theoretical problems and do not contribute as largely as they might to the practical matters of curing disease and saving life. In reply, it may be said that clinicians in all branches of medicine are extremely slow to accept and apply the discoveries made by physiologists. In this complaint both sides have the same good excuse. For even after a new physiological principle has been discovered and its practical importance recognized, it is often an extremely difficult problem, requiring time, money, and patience, to work out its effective clinical application. The practical problem of administering carbon dioxide is not simple, for the various conditions to which it is applied require various special techniques, with or without rebreathing, with oxygen or merely air, with a mask or a tent, for the fire brigade, the surgical operating room, or the bedside. As Sir Michael Foster once said, it is rarely possible to carry a physiological discovery "bleeding from the laboratory to the bedside."

On this account it was only ten years ago that Haggard and I were able to introduce inhalation of carbon dioxide in two distinct practical fields of resuscitation. One of these fields was that of the city fire brigade and the rescue crew in accidents in coal mines. The other was the surgical operating room. These two enterprises have developed separately, although along parallel and now converging lines. I will therefore tell the two stories separately.

RESUSCITATION FROM ASPHYXIA

In America city gas generally contains about 30 per cent. of carbon monoxide. Nearly every family has a motor car, and the exhaust gas contains about 7 per cent. carbon monoxide. In all American cities deaths from carbon monoxide asphyxia, often suicidal, are common. In New York City there are about five hundred a year.

Haldane early showed that the compound which carbon monoxide forms with haemoglobin is dissociable, and that haemoglobin is restored to normal condition under the mass action of oxygen. It was long supposed that the logical treatment for carbon monoxide asphyxia must be the administration of oxygen. But experience on the victims of asphyxia and on animals in my laboratory showed that in many cases the breathing becomes greatly depressed, a deeply asphyxiated man or animal does not draw the oxygen into the lungs in sufficient quantity, and the inhalation of oxygen alone does not quickly displace carbon monoxide from the blood. We found, however, that when carbon dioxide of 5 to 8 per cent. is administered to such cases respiration is greatly stimulated. When a mixture of oxygen and carbon dioxide is administered after a short but intense asphyxia the effects are truly extraordinary. A workman may be overcome in a trench over a leaking gas pipe, or at a blast furnace. He may be non-breathing and nearly pulseless. The inhalation of a mixture of oxygen and carbon dioxide is initiated under prone-pressure artificial respiration. As the carbon dioxide reaches the lungs natural breathing quickly returns, and, after half an hour of inhalation, the man is not only resuscitated, but feels well again and goes back to work. The inhalation not only eliminates carbon monoxide, it also restores to the tissues of the body the normal content of carbon dioxide lost during the development of asphyxia. With the restoration of carbon dioxide the general tonus of the body returns.

After longer, although less intense, asphyxiations resuscitation is not so rapid. But in these cases there is another effect of great importance for the subsequent development of pneumonia is prevented. Before inhalational treatment was introduced pneumonia was a very frequent sequel of asphyxia and was often fatal. The [illegible] to which this treatment has led

* A paper read before the Section of Physiology, British Association for the Advancement of Science, London, September 29th, 1931.

is that the inhalation of carbon dioxide in oxygen not only relieves asphyxia, but also prevents post-asphyxial pneumonia. This is a fact big with promise.

There are now many thousand inhalators in active use in American cities. There are between three and four hundred in New York, and the number is rapidly increasing. In some cities physicians frequently ask for the help of the rescue crews of the fire brigade or the city gas company with their inhalator in cases of pneumonia. Even more often they call for the inhalator for newborn babies that fail to breathe effectively.

Out of this experience has come a clearer conception than we have had heretofore regarding the state of the asphyxiated respiratory centre both in the newborn child and in persons who have been immersed almost to drowning. It has always been supposed that there must be an overpowering excess of carbon dioxide in the blood *in such cases. But our experience now demonstrates* that it is not excess of carbon dioxide, but deficiency of oxygen, that induces the depression of the centre. No very great excess of carbon dioxide is, or can be, produced when the supply of oxygen is shut off. The asphyxiated centre is like one deeply morphinized. Its sensitivity is decreased ; its threshold for carbon dioxide is abnormally elevated. But the inactive centre promptly becomes active again if the amount of carbon dioxide supplied to it is sufficient to stimulate. Accordingly, we find that when the normal 5 per cent. of carbon dioxide pressure is insufficient to stimulate, 7 per cent. carbon dioxide is often effective ; or 10 per cent., or even higher pressures, may be needed. When sufficient carbon dioxide is administered to reach the elevated threshold and to overcome the decreased sensitivity, then spontaneous respiration begins. As the oxygen supply is renewed the threshold drops again to normal, the sensitivity of the centre is restored, natural breathing returns, and the asphyxiated newborn child or drowned person is resuscitated.

In American maternity hospitals, now, the old barbarous and often ineffective methods of resuscitating the newborn by swinging, spanking, and dipping in cold water are being replaced by inhalation of carbon dioxide. As much is used as may be necessary to start breathing, usually 7 per cent., mixed with oxygen. Many babies that cannot be resuscitated in any other way are thus saved. This improvement is also making its way in England, for among the first to adopt it was Dr. Louise McIlroy, at the Royal Free Hospital in London.

Recently another advance has been made. In addition to the four babies in every hundred births that are stillborn, some of whom can, however, be saved by inhalational treatment, there are four other babies that breathe for a few days but die in the first few weeks of life. Until recently no efforts have succeeded in reducing this huge mortality ; for the decrease of infant mortality effected in recent years has been confined to the period after the first month. A large part of the neo-natal mortality is a consequence of continuing atelectasis. The lungs are not fully dilated by the first cry, or for many hours or even days after birth. The ancient practice of making a child cry several times a day is often ineffective in overcoming atelectasis. It has now been shown by Cruikshank that the majority of neo-natal deaths are due to pneumonia developing in undilated areas of the lungs. Combining this fact with other evidence, I have proposed that the lungs of every newborn child should be fully dilated by inhalation of carbon dioxide in the first few days of life. In maternity hospitals where this measure has been adopted mortality from pneumonia has ceased.

Experience in cases of drowning is affording similar evidence. Inhalation of carbon dioxide and oxygen has proved to be not only a valuable supplement to manual prone pressure artificial respiration, but also an effective preventive of the pneumonia which often causes the deaths of persons rescued from drowning.

Prevention of Post-Operative Pneumonia

I turn now to the companion story of carbon dioxide inhalation in the surgical operating room. For many years I urged this inhalation ; and it gradually came to be recognized as a procedure promoting the elimination of the anaesthetic, diminishing nausea, and restoring a vigorous heart action. It is also the most effective method of controlling an exhausting hiccup. Now another advantage has developed. Almost simultaneously three years ago in several clinics in America and also in Germany it was noted that patients who received this inhalation after operations and anaesthesia were free from the otherwise considerable risk of post-operative pneumonia. Even in the best practice the mortality from post-operative pneumonia has been four for every thousand major operations. The number that have had pneumonia and recovered has been many times greater ; indeed, some degree of pulmonary involvement has occurred probably in as many as one in ten, or even one in five, of all cases after surgical operations, especially those in the abdomen. But now in clinics which have adopted as a routine procedure full dilatation of the lungs by inhalation of carbon dioxide, all pulmonary complications, such as in the past have led to post-operative pneumonia, have been eliminated. The reason for this result throws light on problems that have still to be solved.

Several observers in the last century, and particularly the English physician Pasteur early in this century, described a condition following bronchitis or diphtheria in which a part or the whole of one lung collapses and returns to a state like that before birth. But it is only since the use of the *x* ray and the bronchoscope became common that this condition in the lungs, from which post-operative pneumonia starts, has been generally recognized. This is the massive collapse of a lung or the atelectasis of a lobe or lobules. It is now only three years since the relation of atelectasis to pneumonia was first demonstrated experimentally by Coryllos. This demonstration goes far to explain why the victims of motor and other accidents, whose ribs are broken and whose chests are partially immobilized, rather often develop pneumonia.

Normally the lungs are kept constantly expanded and their airways open. Through these tubes they are the best-drained organs in the body. The force which keeps them open is the tonus of the diaphragm and the other muscles of the thorax. Whenever this tonus is lowered, as it is after asphyxia, anaesthesia, immersion, and in elderly and debilitated patients long confined to their beds, and in those who have suffered chest injuries, the vital capacity of the lungs is diminished. In the unaerated areas mucus accumulates until some of the airways are filled and closed. If there happens to be present also inhaled foreign material or catarrh from bacterial invasion, these conditions also contribute to the blocking of airways. As soon as any part of a lung is thus shut off, the air within it *is absorbed into the blood* ; for the total pressure of all the gases in the venous blood is always forty to sixty millimetres less than the total pressure *in the arterial* blood, which is the same as in open areas of the lung, and in the outside air. The occluded lung or lobe or lobules are soon collapsed, and in such collapsed areas any bacteria that happen to be present find conditions favourable for their growth and activity. It is in this way probably that all secondary pneumonias develop.

This conception assigns to the tonus of the skeletal muscles of the body a place of prime importance in

respiration. It is this tonus that keeps the lungs expanded and prevents atelectasis. The movements of respiration do not consist merely in the alternate contraction and relaxation of the thoracic muscles. In reality, as W. R. Hess expresses it, these muscles pass at each breath from one tonus level to another and back again. When respiration is depressed the tonus level of the entire musculature of the body is depressed also. The capacity of the thorax is greatly decreased by the relaxed and elevated diaphragm and the flaccidity of the other respiratory muscles. In the partially deflated lungs atelectasis readily develops, and, if infection is present, pneumonia may follow.

When, on the contrary, respiration is stimulated, as it is in normal muscular activity by an increased production of carbon dioxide in the body, or as it is by inhalation of carbon dioxide, the tonus of all the muscles of the body, and particularly those involved in respiration, is increased. The lungs are expanded, occlusion of airways is prevented, and any airways that have already been occluded are reopened The normal drainage from the lungs through the airways is maintained, or re-established, and the development of a secondary pneumonia is prevented.

Even in the development of primary pneumonia low muscular tonus, partial deflation of the lungs, and the resulting atelectasis probably play an important part; for it is a well-recognized fact that lobar pneumonia may spread from patient to patient in the beds of a hospital, but that the physicians and nurses, who are moving about and keeping their lungs expanded, are relatively immune to the contagion.

If the length of this address permitted it could be shown that respiration exerts its chief effect upon the circulation also through its influence upon the tonus of the musculature of the body. This tonus is the chief factor in the veno-pressor mechanism—a mechanism largely distinct from the vasomotor system and scarcely less important. It is the tonus of the skeletal muscles which normally presses the blood out of the tissue capillaries into the veins and back to the right heart. Whenever respiration is stimulated, as it is by physical exercise, the increased tonus of all the contractile tissues increases the volume of the venous return, improves the heart action, and augments the circulation.

When, on the contrary, respiration and muscle tonus are depressed, the blood stagnates in the tissues, the venous return is diminished, the heart action is weakened, and the circulation is retarded. The extreme form of such depression is surgical shock. The inhalation of carbon dioxide after anaesthesia and operation, and in other conditions of lowered vitality, by restoring respiration and muscle tonus, counteracts both the depression of the circulation and the tendency to atelectasis and pneumonia.

Such in brief outline are the contributions which the physiology of respiration is making to the science and art of resuscitation. From the developments of the past few years it appears probable that in the near future all secondary pneumonias will be preventable.

Conclusions

In cases of drowning, asphyxiation, and other accidents and after surgical anaesthesia, the prevention of secondary pneumonia is almost as important as the immediate resuscitation Inhalation of carbon dioxide mixed with oxygen or with air is the most effective means of stimulating respiration. This inhalation has proved to be also a highly effective preventive—indeed, it is essentially the specific preventive—of the collapse of the lungs which leads to pneumonia. These two advantages have now been demonstrated by experience in large numbers of cases of carbon monoxide asphyxia, drowning, and other accidents In the asphyxia of the newborn this inhalatio[illegible] placing the old brutal and often ineffective methods of swinging, spanking, and dipping. In surgical clinics this treatment is used to counteract failure of breathing under anaesthesia, to restore a normal circulation, and especially to prevent post-operative pneumonia.

Respiration is closely associated with the tonus of the muscles, especially of the thorax. Depressed breathing and low tonus permit collapse of parts or the whole of a lung. From this collapse, if infection is present, pneumonia develops. If respiration and muscle tonus are stimulated by inhalation of carbon dioxide the lungs are kept open and the development of pneumonia is prevented.

DIABETES INSIPIDUS FOLLOWING FRACTURED SKULL

BY

A. PATRICK, M.B., F.R.C.S.Ed.

HULL

Diabetes insipidus, a comparatively rare condition, has been recognized since 1674, when Willis noted that in a certain number of cases which were classed as diabetes mellitus the condition of the urine was different, in that it did not have the same sweet taste. This suggested to him a basis of differentiation. It was not until one hundred years later that Simmons described two cases of this disorder, and these were published in detail by Fitz. Following this, Frank referred to diabetes insipidus as "a long-continued abnormally increased secretion of non-saccharine urine, which is not caused by a diseased condition of the kidneys."

Although this malady was definitely recognized by clinicians, nothing was known of its etiology except that it was not due to renal disease. The nineteenth century literature contains several articles dealing with experimentally produced diabetes insipidus Claude Bernard, in his experimental puncture of the floor of the fourth ventricle, produced this syndrome, and believed that he had found a centre in the base of the brain which governed it. If diabetes insipidus is due to some disturbance of the pituitary, as we have every reason to believe, then the experimental work of Schafer, Magnus, and Herring and the deductions and observations of Cushing, are invaluable Briefly, Schafer, in 1902, proved that a polyuria in animals could be experimentally produced by the injection of pituitary extract Other experimental work showed that the diuretic action of the pituitary extract was caused by the pars intermedia. At the same time, Cushing noted that in a certain number of his operation cases in which the pituitary body was subjected to manipulation a severe polyuria frequently resulted, which

lasted for several days. He believed that this was due to a hyposecretion of the posterior lobe of the pituitary.

A great number of pathological conditions are put forward as the cause of diabetes insipidus. The commonest of these are: tumours of the pituitary body, tumours of the base of the brain, head injury, acute infectious diseases, tuberculosis, and syphilis. The two main theories advanced as the cause of diabetes insipidus are: (1) the endocrine theory, and (2) the nervous theory. According to the endocrine theory the syndrome is manifested by a lack of pituitary hormone in the blood, due either to diminished production or to deficient absorption. According to the nervous theory, the condition is due to some disturbance of the hypothalamic region. Croll has shown that the pars intermedia of the pituitary is richly supplied with nerves. Greving and Pines have described nerve tracts from the hypothalamus to the pituitary: any interference with this nerve supply is evidenced by pituitary disturbance. Whatever may be the pathology, the determining factor is the functioning power of the pituitary body.

Records of some of the American hospitals show that there have been no authentic cases. Rowntree of the Mayo Clinic, Rochester, states that of 257,000 hospital admissions, 35 were indexed as diabetes insipidus, but on careful study he disregarded 11 of these. Fitz recorded an incidence of 14 cases per 100,000, and Williams's statistical review shows the incidence to be 19.2 per 100,000. It is more common in youth and in the male sex. Of 85 cases quoted by Strauss 57 occurred under the age of 25; and of 36 cases quoted by Moffat and Greenberger 28 were males and 8 were females.

The symptoms and signs of diabetes insipidus are varied. The diagnostic features of the condition are: (1) the uncontrollable thirst, and (2) the polyuria, the urine being of low specific gravity. The other features which may be present are a subnormal temperature, slow pulse rate, low blood pressure, somnolence, irritability, lack of appetite, constipation, and dry skin. These symptoms are by no means constant in every case. The patient may complain of none other than the thirst and polyuria, describing the condition more as a nuisance than as an ailment. On the other hand, some patients may become worried and depressed, and melancholia has been known to result. Ocular symptoms which may arise during the course of the disease are usually due to the pressure effects resulting from the tumour. *X*-ray appearances of the sella turcica are, as a rule, not very helpful, except in cases where there is tumour formation. The polyuria is invariably the first sign, and the thirst is consequent upon the polyuria. The quantity of urine passed varies considerably, as much as 20 pints being voided in twenty-four hours. It is of very pale colour, and the specific gravity is always low, practically never above 1010. The reaction is faintly acid and the percentage of solid constituents small. The prognosis depends essentially upon the causal lesion. If this is a head injury the prognosis is relatively good. If it is a tumour the outcome is fatal and the disease invariably of short duration. Where syphilis is the cause anti-syphilitic treatment gives beneficial results. In the idiopathic cases where no definite lesion can be detected the patient, although responding well to treatment, may drag on for years, and death may ultimately be due to some other disease. Hypodermic injection of pituitary extract gives the most satisfactory results. The urine is greatly diminished, the blood pressure rises, the pulse quickens, and irritability and somnolence disappear. One must be guided more by the alleviation of the thirst than by the quantity of urine passed. The amount of extract used varies, and, at first, is best given in two separate doses, as its effect lasts only about eight hours. As soon as the patient wakes in the morning he should be given a hypodermic injection of pituitary extract, and this is followed by a second dose in the evening. With the co-operation of the patient one can arrive at the correct dosage to keep the condition under control. With improvement, less pituitary extract can be given and the time between the injections lengthened. Feeding the patient on fresh pituitary gland may be useful. Such a method, of course, is not practicable in the smaller towns or villages. Motzfeldt quotes a case where he fed his patient on seven fresh glands daily. Under this treatment improvement was so marked that in eighteen months' time the condition could be kept under control with one gland per day. Lumbar puncture has been used in certain cases, especially in that type due to tumour formation and serous meningitis. Such treatment, of course, gives only temporary relief. Anti-syphilitic treatment in the syphilitic type of case gives satisfactory results.

History of Case

On October 6th, 1930, a male, aged 21, was admitted to a nursing home suffering from fractured anterior and middle fossae of the base of the skull as a result of a motor accident. (The *x*-ray photograph showed an extensive fracture, commencing high up in the right temporal fossa and running down into the base of the skull into the regions of the anterior and middle fossae.)

On admission he was in a dazed condition; both eyes were swollen and discoloured, and he bled from the right ear and nose. The following day he complained of loss of vision in the right eye, together with deafness in the right ear and headaches. During the first few days the patient showed signs of improvement. The quantity of urine passed was estimated at 45 ounces +, and of specific gravity 1014; there was only a trace of albumin. About a week after admission he became rather drowsy and irritable, and he complained of thirst. His urine was now 100 ounces + per day. No active treatment was instituted at this time. He was carefully observed from day to day, and on October 24th the thirst had greatly increased, the quantity of urine passed being 160 ounces +. He was very irritable, and at times drowsy. His bowels were constipated, and his skin dry; the temperature was 97°, pulse rate 48, respiration rate 12. He stated that his thirst was insatiable, and on one occasion, so great was his craving, he secretly got out of bed when he was unattended and drank the water in the wash-basin. On the 25th hypodermic injections of pituitary extract were commenced. The results were spectacular. The initial dose given was 1 c.cm. twice daily. His thirst diminished and the polyuria decreased, the total amount of urine passed in the twenty-four hours following treatment being 59 ounces. The temperature rose to 98.4°, the pulse rate gradually increased to 68, and his respiration rate to 14. With the co-operation of the patient the dose of pituitary extract was diminished to 3/4 c.cm., given the first thing on awaking in the morning and the last thing at night. This, the patient stated, gave him total relief from all his symptoms.

He was discharged on November 10th, 1930, with instructions to carry out the pituitary treatment under his own medical adviser's observation.

The case presented illustrates many important and interesting features. I believe that the cause of the diabetes insipidus in this patient was the fracture involving the middle fossa; presumably it passed through the sella turcica and in some way injured the pituitary body. It is probable that, as a result of haemorrhage, there was pressure on the pituitary gland, causing interference with its function. The fact that the condition was not manifested until a week after the accident proves that the pituitary body was not directly injured at the time of the accident, and that its dysfunction was caused by something else. This, in my opinion, is a very useful point in the prognosis, which, had the disorder been due

to a direct injury, would have been very much worse. As this haemorrhage is absorbed so will the function of the pituitary increase, and the patient already shows signs of improvement in that less pituitary extract is required to control the thirst and polyuria. The necessity for early recognition of diabetes insipidus cannot be too strongly emphasized, as the polyuria in time has a deleterious effect upon the kidneys and bladder. Pituitary extract hypodermically is without doubt the treatment of choice, but it must be remembered that it is not a cure. The treatment must be maintained and the co-operation of the patient sought.

In conclusion, I desire to express my indebtedness to Mr. Blair for the facilities he has afforded me in observing this case.

CONGENITAL PYLORIC STENOSIS*

BY

C. MAX PAGE, D.S.O., F.R.C.S.

SURGEON TO ST. THOMAS'S HOSPITAL AND THE VICTORIA HOSPITAL FOR CHILDREN

Although the morbid anatomy and clinical features of congenital hypertrophic stenosis were clearly defined by Hirschsprung in 1888, no striking advance in the treatment of the condition was effected till the introduction in 1913 by Rammstedt of the simple operation of section of the sphincter. Till then treatment was essentially medical Surgical intervention was only given a chance in obstinate cases and was associated in general with a mortality rate of about 50 per cent., although a few operators using Loreta's method of dilatation quoted better results. With Rammstedt's operation the reported mortality varies from 5 to 25 per cent., and it has become almost the standard method of treatment.

It is noticeable in the literature, however, that the swing-over to surgical treatment has by no means been general, particularly in Germany and Denmark. As late as 1927 Professor Monrad of Copenhagen reported 228 cases of the condition all treated medically and with an over-all death rate of only 14·4 per cent. It may therefore be a matter of dispute how far the extended use of the operation has reduced the mortality. One undoubted advantage it has by common acceptance—namely, the shortening of the period of treatment. The wide variation in the mortality reported by various observers shows that the problem is affected by several factors. Both pre-operative and post-operative treatment influence the result as much perhaps as the method of operation.

The fact that I am allowed to open this discussion is, I think, evidence of how far in this country radical surgical treatment has been accepted. I would emphasize, however, that the surgeon plays only a small, if important, part in bringing these cases to a successful issue. The direction of the pre-operative and post-operative treatment requires the greatest judgement and care of a skilled paediatrician if satisfactory results are to be obtained. As opener I propose to outline the general points in relation to diagnosis I shall consider in some detail the operative technique and its bearing on results, leaving it to those who follow me to consider in detail the more difficult medical and biochemical problems on which they are so much better qualified to speak.

Symptoms and Diagnosis

The cause of the pyloric hypertrophy remains a matter of speculation. The fact that it is commoner in males than in females (4:1) and in the first-born is accepted. Although obstructive symptoms are seldom in evidence till the second week of life, it would seem probable from the size of the tumour even at the earliest stage that the hypertrophy develops during intrauterine life. The youngest patient I have operated on for the condition was 18 days old, and the oldest was 6 months. It does not seem to me to be necessary to discuss whether spasm and stenosis of the pylorus should be distinguished. In my experience some degree of hypertrophy is present in all cases, and even in its fully developed form symptoms are produced by spasm and not stenosis in its true sense.

The points determining diagnosis are, I think, well established, and do not provoke controversy. It is based on the presence of repeated projectile vomiting, visible peristalsis of an enlarged stomach, coupled with wasting and constipation developing about the second week of life in an infant till then apparently normal. A tumour may be felt at the pylorus, but evidence of this is certainly not necessary to establish the diagnosis. I have noticed at operation wide variation in the size and consistence of the tumour and also in the depth at which it lies under the liver. Radiography gives interesting pictures for study and definite evidence of the degree of obstruction, but it is not essential as a routine diagnostic method.

When to Operate

The decision as to when a case should be operated on is no doubt difficult, and will vary with the facilities available. My own impression is that once the full range of symptoms above described is established, the sooner operation is carried out the better will be the results. I think my colleague, Dr. Jewesbury, who has passed on to me the majority of the 150 cases I have operated on, takes this view. If serious emaciation has developed, the risk of operation is certainly gravely increased.

Treatment Before Operation

Pre-operative preparation should, I think, consist in regular washing out of the stomach for a few days and the administration of subcutaneous glucose saline for a simila period. Regular small feeds of a suitably diluted mil given at two-hour intervals are continued. I do not know how far the administration of atropine is useful, and I shall be interested to hear the views of those who follow me on this subject. To them I shall leave the fuller discussion of this problem and the strictly medical treatment, as they are better qualified to express an opinion.

Operative Technique

It is clear that the choice and administration of the anaesthetic in these infants with so frail a hold on life is a matter of importance Gray and other surgeons at the Great Ormond Street Hospital consider gas and oxygen to be the best In Germany chloroform seems to be popular It was used by Kirschner, who records 15 cases without any deaths Pauchet prefers local anaesthesia. In my own experience light ether anaesthesia given on an open mask has been satisfactory. It is certainly simple to give and readily controllable. In two cases in which death

* Read in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association at Eastbourne, 1931.

followed closely on operation it was observed that the anaesthesia had been carried to the full degree of relaxation. This, I think, is to be avoided. The operation can be easily performed without full muscular relaxation, although irregular respiratory movements are undesirable during the few minutes the peritoneum need be open. I have carried out the operation under local anaesthesia in three cases, but I think that the movements of the infant and the tendency to the extrusion of the fine omentum and viscera add unnecessary shock and difficulties to the procedure.

I make a vertical incision about one inch in length, half an inch to the right of the mid-line situated half-way between the xiphisternum and the umbilicus. The rectus muscle is split and the underlying peritoneum opened to the full extent of the wound. This exposes the right lobe of the liver. An incision lower down may make delivery of the pylorus easier, but it does not control the other viscera so well either during operation or during the healing period. The lower angle of the wound is then drawn down with a retractor, the distended pyloric antrum thus coming into view. This is drawn out of the wound with forceps and will lead to the pyloric tumour. The delivery of the latter is generally easy with gentle traction by a rat-toothed forceps, but sometimes it is less mobile, and a special ring forceps may be convenient in order to bring it to the surface. The section of the peritoneum and superficial muscle fibres of the tumour is made with a knife, the pylorus being held between the thumb and finger of the left hand. The division of the sphincter is completed with a blunt dissector. There can be no doubt when the section is complete, as the white mucous membrane prolapses into the wound. Care should be taken at the duodenal extremity of the swelling not to puncture the mucous membrane, as at this situation the muscle tumour stops abruptly. On its stomach side the line of demarcation from the normal musculature is gradual and no harm is done by extending the incision well on to the pyloric antrum. The section is made along a line on the pyloric tumour where the surface vessels cannot be seen. If this line is chosen and if the division is completed with a blunt dissector, I do not think there is any need to control the haemorrhage by ligature. If a bleeding point of any size is seen it can be under-run with fine gut. In my experience the necessity for this is very unusual. The pyloric tumour is then slipped back into the abdomen and the wound sewn up in two layers with continuous fine catgut. The section is sutured with interrupted salmon-gut sutures. The operation performed in this way takes about five minutes from start to finish. It should not involve exposure of any viscus other than the pyloric end of the stomach.

After-Treatment

In after-management the feeding is important. It must be remembered that, though the stricture has been divided, a dilated and hypertrophied stomach is present, and there may be some mild infection of the gastro-intestinal tract. Regular and dilute feeds are given from within an hour or two of the operation. A little vomiting is not uncommon in the first day or two, though it seldom reaches the projectile type.

Complications

The complications from the surgical standpoint which may be met with are: wound infection, prolapse of viscera, recurrent vomiting, hyperpyrexia, broncho-pneumonia, and gastro-enteritis.

A mild degree of infection of the wound is more common than one would expect. It may take the form of a mild red infiltration. I think this must be due to the irritation of the catgut. I shall be interested to hear the views of other surgeons on the question of suture material for these cases. I have observed prolapse of omentum in one case and prolapse of gut in another. In the first instance, through-and-through sutures only had been employed to enclose the abdominal wound, and a fragment of omentum prolapsed between two of them. The omentum was ligatured and cut off flush with the wound, and no fresh complications were observed, the patient making a normal recovery. In the other instance the wound suppurated and broke down about the fifth day, allowing prolapse of stomach and intestines. Re-suture was promptly carried out, but the child died of general peritonitis three days later. I notice in the literature that recurrent vomiting of a projectile type has been recorded with some frequency. In my experience it has only once been necessary to reopen the abdomen and carry out a secondary operation. In one fatal case relief of stenosis was incomplete; no secondary operation had been performed. As I mentioned above, a certain amount of forcible vomiting may occur for a day or two, and need not cause alarm. some measure of hyperpyrexia is observed in about 10 per cent. of cases operated on. I am not quite clear about its significance. In one case the temperature rose to about 108°, and the baby died on the second day. In other instances it has risen to 106° and 107°, and has been brought down by sponging; it does not appear to have interfered with a successful result. Broncho-pneumonia was responsible for two deaths at a fairly early stage subsequent to operation. I do not think it common enough to contraindicate the use of ether, though no doubt these fatalities may be quoted as an argument against its use. Gastro-enteritis was the cause of death in two cases. In regard to this latter complication, it has been very much less in evidence since operation has been undertaken at an earlier stage and the after-treatment has been somewhat modified.

In regard to the function of the stomach and the condition of the children after this operation—as far as cases under Dr. Jewesbury have been observed—it appears that the child becomes normal both in physique and in its digestive functions.

Mortality

The 150 cases in which I have operated, from 1922 up to date, may be divided into two groups, namely, 60 carried out at the Victoria Hospital and Princess Mary Home, and 90 cases at St. Thomas's Hospital. It is interesting to note that the mortality in the first series averages 6.6 per cent.; in the St. Thomas's cases it is 12.2 per cent. It is not altogether easy to explain the difference in results, as the surgical and medical treatment was carried out on the same lines, though it is perhaps true that a larger number of cases at St. Thomas's came under care at a late stage of the condition, but it brings home to one the difficulty in drawing conclusions from a small group of figures. I would quote as a further example of this the fact that in 1924-1925 at St. Thomas's 14 successive cases were operated on without any fatality.

Conclusion

To sum up, I think one may say that the modern surgical treatment, if it is applied early and associated with vigilant medical supervision and skilled nursing, may be expected to reduce the mortality of this condition to 5 to 10 per cent. This estimate may not appear to be very optimistic, but it should also be remembered that the treatment curtails very greatly the period of hospitalization.

PREMEDICATION*

BY

STANLEY ROWBOTHAM, M.R.C.S., L.R.C.P.

ANAESTHETIST, ROYAL FREE HOSPITAL AND WESTMINSTER HOSPITAL

For the purpose of this discussion, by *premedication* is understood a new conception of pre-anaesthetic medication, whereby the patient is rendered unconscious in his bed before the administration of the anaesthetic. The drugs employed for this purpose, and the technique of their administration it is the object of this meeting to consider. The method has been aptly named *basal narcosis*.

It is no longer necessary that a man about to undergo an operation shall first of all be subjected to the ordeal of being taken from his bed to the theatre, compelled to witness the preparations for his operation, and then undergo the unpleasant experience of inhaling the anaesthetic until the last threads of his dissociating consciousness finally break. Neither is it necessary that when he once more awakens he shall reek of the anaesthetic, nor be distressed by hours of vomiting.

History

In 1913 Gwathmey introduced a method for the production of narcosis by rectal oil-ether solution; and, although this method had certain disadvantages, it marked a great step forward as far as the patient's mental reactions were concerned. I have always felt that sufficient due has not been given to Gwathmey for recognizing what a tremendously important thing is the abolishing of preoperative fear. Some years later he published a paper on synergistic anaesthesia, which marked the actual birth of basal narcosis as it is known to-day. It was this paper which stimulated me to try several drugs with the object of finding a method whereby a patient might safely be put to sleep while still in bed, and thereby saved the mental distress which often has such a deleterious effect upon his condition before, during, and after operation. I finally decided upon paraldehyde, which had been used by Gwathmey in his oil-ether mixtures. In spite of its disadvantages of smell, and in face of a good deal of opposition, the use of rectal paraldehyde steadily increased for some years.

In 1926 avertin was introduced by Prof. Eichholtz. It is given in 2½ per cent. solution per rectum and is a much more powerful drug than paraldehyde. It lacks the disagreeable smell of the latter and has the additional advantage that it is only necessary to inject a small volume of the solution into the rectum.

Towards the latter end of 1929 barbituric acid and its compounds began to receive consideration both as anaesthetics per se and as complementary or basal narcotics. The barbiturates were well established as narcotics in general medicine. In 1924 Fredet and Perlis reported in the *Presse Médicale* the intravenous use of somnifeine as an anaesthetic. I tried it and was much impressed by the results; but reports that its originators were not altogether satisfied with it, and the fact that some dogs which were anaesthetized for research work also died, caused me to abandon it. I have also tried luminal given by the mouth; in doses of half to three-quarters of a grain per stone weight, and although complete unconsciousness was not obtained, patients were rendered drowsy and required less anaesthetic. It is to American workers that we owe the introduction of the newer, quickly acting barbiturate compounds, amytal and nembutal. Pernocton, of German origin, is very like the latter. Without being unduly enthusiastic, I think one may say that these compounds (and especially nembutal) have already proved of great value as basal narcotics; and I feel certain that they will be widely used in the future. They were introduced into this country by Magill, who brought supplies of amytal and nembutal back with him after his visit to America with the British Medical Association last year, and it is to him that I owe my introduction to these drugs.

I propose briefly to consider each group of drugs, mentioning their characteristics and giving typical illustrative cases from my own experience; detailing also cases in which I have seen adverse symptoms. I shall purposely refrain from expressing any opinion as to the comparative value of the different drugs until the end, so that the descriptions may be as unprejudiced as possible.

Paraldehyde

Except in young children and very old and debilitated subjects, paraldehyde alone will not produce unconsciousness. The addition of morphine or some other such drug is needed. Patients are graded into four groups. (This classification may also be of help in deciding the dose of other narcotic drugs.)

Group 1.—Children under 7. Debilitated or severel toxic subjects. Patients with a high temperature.

These cases receive 1 drachm of paraldehyde per stone weight three-quarters of an hour before operation. The solubility of paraldehyde in water is 1 in 10, so that every drachm of paraldehyde is dissolved in 10 drachms of warm saline. This is shaken hard in a bottle to ensure solution and run slowly into the rectum by catheter and funnel; the rectum having been cleared by saline enema at least two hours previously. If the patient becomes unconscious during the introduction of the solution further administration is stopped; but this only applies to Group 1. Atropine is given hypodermically where an anaesthetic other than gas and oxygen is to follow.

Group 2.—Normal adults and children over 7.—One and a quarter hours before operation the patient receives hypodermically morphine Gr. 1/40 for every stone weight, followed in fifteen minutes by rectal paraldehyde, 1 drachm per stone weight.

Group 3.—Alcoholics. Athletes over 25 years of age. Very nervous patients. These patients receive on the night before operation (repeated during the morning, if the operation is in the afternoon) a full dose of bromide and chloral or bromidia. One and a quarter hours before operation: morphine, Gr. 1/40 per stone weight, combined with hyoscine hydrobromide, Gr. 1/150-1/100 hypodermically. One hour before operation: paraldehyde, 1 drachm per stone weight.

Group 4.—Thyrotoxic cases. A preliminary trial of the patient's reaction to hyoscine should be made some days previously as it sometimes causes great excitement. Preliminary sedatives—bromide and chloral, and morphine and hyoscine (if not contraindicated)—are given as for Group 3. Owing, however, to the fact that paraldehyde may not be sufficient to produce sleep, it may be necessary to follow on with ether. The paraldehyde is, therefore, dissolved in olive oil—half an ounce of oil to every drachm of paraldehyde—and if the patient be still awake half an hour before operation, one-half to two ounces of a 50 per cent. mixture of ether and olive oil is run into the rectum, in half-ounce doses, at intervals of five minutes, until he falls asleep. This is not, of course, an unvariable dosage; it is necessary to sum up a case, and a certain amount of experience is necessary. Most patients retain the rectal injection without trouble, but a suppository of chlorotone gr. x is of help in this respect. The average case is asleep in from 20 to 25 minutes, but some take as long as 45 minutes; the rate of absorption from the rectum varies.

* Read in opening a discussion in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Eastbourne, 1931.

Illustrative Cases

Male aged 48.—Operation for double radical antrum. Heart, second pulmonary sound accentuated, nil else abnormal. Blood pressure, 140/90. Chest, hyperresonant, emphysema. Weight, 12 st. 8 lb. Plethoric, drinks fair amount; big smoker; muscular; fat. Night before operation: bromidia 5ijss. 7.45 a.m., morphine gr. $\frac{1}{3}$, hyoscine gr. $\frac{1}{100}$ and atropine gr. $\frac{1}{100}$. 8.0 a.m., paraldehyde 5xij in saline ℥xv per rectum. 8.30 a.m., asleep; blood pressure 130/90. 9.0 a.m., anaesthetized, tracheal tube passed with ease using only gas and oxygen. 10.0 a.m., returned to bed, colour good, blood pressure 120/75. Slept without moving until 6 p.m.; somewhat restless until 8 p.m.; received morphine gr. $\frac{1}{6}$ and slept until next morning, when he awoke asking when operation was going to take place.

Soldier aged 39.—Operation: partial gastrectomy. Heart and chest, nil abnormal. Blood pressure, 120/65. Weight, 10 st. 6 lb. Thin, active man. Night before operation: pot. brom. gr. xxx. 7.45 a.m., morphine gr. $\frac{1}{4}$ with atropine gr. $\frac{1}{100}$. 8.0 a.m., paraldehyde 5xss in saline ℥xiv, per rectum. 8.30 a.m., asleep; blood pressure 100/60. 9 a.m., anaesthetized with gas-oxygen-ether, relaxation obtained with very little ether. 10.30 a.m., returned to bed, colour good, pulse 120, blood pressure 90/60. 4 p.m., still asleep, colour good, pulse 100, blood pressure 95/70. Slept until 3 a.m. No vomiting. Convalescence uneventful.

Girl aged 8.—Operation: tonsillectomy. Physical examination, nil abnormal. Tall big child, weight 6 st. 7.45 a.m., morphine gr. $\frac{1}{6}$ with atropine gr. $\frac{1}{100}$. 8.0 a.m., paraldehyde 5v in saline ℥vii. Asleep almost immediately after paraldehyde was run in. Pulse 120, soft; respirations shallow. 9.0 a.m., anaesthesia with 50/50 mixture of gas and oxygen; operation performed without event. 9.45 a.m., returned to bed, breathing very shallow, colour poor. Oxygen administered; bad colour without oxygen. Lobeline gr. $\frac{3}{10}$ hypodermically—colour and breathing improved. Patient remained asleep until 8 o'clock next morning, very drowsy all next day. Uneventful recovery. This child was wrongly graded, and should not have received the morphine.

Boy aged 5½.—Operation: tonsillectomy. Physical examination, nil abnormal. Very fit little boy, weight 2 st. 8 lb. 8.15 a.m., paraldehyde 5ij in saline ℥iij. 8.40 a.m., asleep, colour good, pulse 98. 9 a.m., anaesthetized—gas and oxygen with very little ether at start only. 9.30 a.m., back in bed, colour good. 10.30 a.m., somewhat restless, condition good. 12 noon, crying, periods of sleep. Seen at 4 p.m., awake, condition good, vomited twice.

Avertin (Tribromethylalcohol)

Avertin is a white crystalline powder which is only soluble 1 in 28 of water. If heated above 40° C. it decomposes and dibromacetaldehyde is formed, which will cause injury to the rectal mucosa. Like paraldehyde, it is administered by the rectum. Immediately before use the solution must be tested to make certain that no decomposition has occurred. For this purpose Congo red 1:1000 solution is recommended by the manufacturers. It should remain orange red. Any trace of blue tint would indicate decomposition, and the solution should be discarded.

Avertin is very quickly absorbed by the intestinal mucous membrane. It is largely excreted through the kidneys, and to a less degree by the liver. It was originally available only in powder form, and the time required for the preparation of the solution was a great disadvantage. The manufacturers now sell a solution which is kept stable by the addition of amylene hydrate. Each c.c. of the solution contains one gram of avertin. From this a 2½ per cent. solution is prepared with distilled water at 37° C. Dosage varies from about 0.05 to 0.15 grm. per kilogram body weight, the average dose being about 0.1 grm. per kilo.

Using the classification already described my average dosage was approximately as follows: Group I, 0.05 to 0.08 grm. per kilo. Group II, 0.1 grm. per kilo. Group III, 0.12 grm. per kilo. Group IV, 0.12 with the addition of morphine, hyoscine, etc. I have never exceeded a dose of 0.12.

An enema the night before is desirable but not absolutely necessary. Morphine given an hour before operation enables one to obtain narcosis with smaller doses of avertin, but is objected to by some workers on account of respiratory depression.

The solution is very slowly run into the rectum half an hour before operation. Excitement is rare, and the patient very quickly goes to sleep in a natural manner, but narcosis progressively deepens for another ten to fifteen minutes. It is quieter and deeper than that of paraldehyde. The patient is relaxed and will more easily lose his airway. In many ways it reminds one of chloroform anaesthesia.

Contraindications are few. Disease of the kidneys and liver, rectal disease, and advanced pulmonary tuberculosis are the chief ones mentioned by German writers; but the patient's condition and the degree of toxaemia present must, of course, be the real guiding factors when deciding for or against the drug.

Recovery of consciousness occurs usually in from 1 to 4 hours; the period depends largely upon the amount of morphine and the anaesthetic used. Restlessness is rare. Frequently there supervenes a period during which the patient, though lying quietly with eyes closed, can talk and take drinks, etc., but will afterwards remember nothing of what has happened during this time. Vomiting rarely ensues, but if it does it is not remembered.

Illustrative Cases

Woman aged 50.—Operation for carcinoma of breast. Heart and lungs, nil abnormal. Weight 8 st. 6 lb.; a small spare "wiry woman." Blood pressure, 130/80. 11 a.m., morphine gr. $\frac{1}{6}$ with atropine gr. $\frac{1}{100}$. 11.30 a.m., avertin fluid 5.3 c.c. in distilled water 214 c.c. (0.1 grm. per kilo); solution shaken hard, tested with Congo red, and slowly run into rectum with catheter and funnel. 11.45 a.m., asleep; blood pressure 90/65. 12 noon, anaesthetic (gas and oxygen only), good pulse and colour throughout. 1.10 p.m., blood pressure at end of operation 90/65. 2.30 p.m., patient moved and spoke, but fell asleep again. 4.0 p.m., patient quite conscious, no vomiting. Uneventful recovery.

Man aged 68.—Operation: oesophagoscopy for carcinoma of oesophagus. Lungs, chronic bronchitis. Heart sounds distant and feeble, pulse soft, 88. General condition, wasted and feeble. 11 a.m., morphine gr. $\frac{1}{6}$ with atropine gr. $\frac{1}{100}$. 11.30 a.m., avertin fluid 5.1 c.c. in distilled water 203 c.c. (0.08 grm. per kilo). 11.40 a.m., asleep. 12 noon, pharynx anaesthetized by cocaine spray; oesophagoscopy performed without general anaesthetic. Patient asleep until 3 p.m. Uneventful recovery.

I have, unfortunately, three other cases to report when the patient died. The first two occurred in 1929—using an early sample of avertin which I obtained from Germany. The third had avertin fluid. The cause of death is not very evident. I am sure the solution of avertin was correctly made and tested; probably the error occurred in gauging the dose, and as will be seen, two were bad risks. Avertin is said to be excreted as bromine, which, in common with the other halogens, I believe is prone to attack the liver.

Last year I anaesthetized a man of 61 for partial gastrectomy—he had avertin (no morphine) followed by ether. His condition was satisfactory until two days after operation, when he collapsed with signs of pneumonia. The only post-mortem findings were hypostatic pneumonia on both sides, and fatty infiltration of the liver throughout. Something akin to delayed chloroform poisoning may be possible. Combined with morphine the respiration becomes depressed; in fact, the condition of the patient reminds one very much of chloroform anaesthesia—shallow breathing, soft pulse, absolute relaxation.

Man aged 68.—Operation for carcinoma of tongue: insertion of radium needles. Heart, second pulmonary sound accentuated, nil else abnormal. Systolic blood pressure, 120. Lungs, chronic bronchitis and emphysema. Weight, 10 st. 2 lbs. 11 a.m., omnopon 1 c.c. (=gr. $\frac{1}{3}$), atropine gr. $\frac{1}{100}$. 11.30, avertin 6.0 grams in distilled water 240 c.c. (This is 0.3 grm. less than 0.1 grm. per kilo.) Asleep on arrival at theatre at 12.15. No anaesthetic needed—patient moved once or twice when needles were inserted, but not enough to prevent, or delay, the operation. Systolic blood pressure 70, pulse 90, volume fair. Patient never recovered consciousness. He became cyanosed in spite of the administration of oxygen, and his pulse became more and more feeble, until he finally died at 2 a.m. next day.

It is perhaps hardly fair to blame avertin for death. The man obviously had too much omnopon and avertin, as

shown by the fact that he needed no other anaesthetic. There may also have been another factor—obstructed airway. Usually tongue cases are intubated and the tube left in until the patient's reflexes have returned and he will no longer tolerate it. In this case no intubation was done; the patient maintained his own airway whilst in the theatre, and the house-surgeon assured me that there was no evidence of obstruction to breathing afterwards.

Woman aged 27.—*Operation*: appendicectomy. Heart and lungs, nil abnormal. Weight 11 st. 4 lb. Healthy woman. 12 noon, morphine gr. ½ with atropine gr. $\frac{1}{100}$. 12.15 a.m., avertin 7.2 grm. in distilled water 290 c.c. (0.1 grm. per kilo). 12.40 a.m., patient asleep; pulse full and regular; no blood pressure records taken. Anaesthetic, nitrous oxide-oxygen-ether. It was necessary to give ether practically the whole time to obtain relaxation. Patient returned from theatre fit, but she never recovered consciousness, her pulse gradually became more and more feeble, and in spite of every restorative measure she finally died at 3 p.m. the following day, 26½ hours after the administration of the avertin. Unfortunately we were unable to obtain a post-mortem examination.

Woman aged 63.—Operation for exophthalmic goitre. Heart, enlarged 4½in. to left of mid-sternal line. Pulse on admission 120, on day before operation 84. Blood pressure, 138/78. Report from physician-in-charge electrocardiographic department: "no contraindication for operation." Basal metabolism rate + 46 per cent. Considerable loss of weight. Weight 8 st. 7½ lb. Typical thyrotoxic patient. 1 p.m., morphine gr. ½ with atropine gr. $\frac{1}{100}$. 1.30 p.m., avertin fluid 5.4 c.c. (0.1 c.c. per kilo) in distilled water 218 c.c. 2.0 p.m., patient not asleep on arrival at theatre. Nurse reported some of avertin solution returned; therefore hyoscine gr. $\frac{1}{100}$ given hypodermically. Anaesthetic: bilateral paravertebral cervical block, 2 per cent. novocain with adrenaline 1: 400,000. During the operation it was necessary to give a little gas and oxygen to keep patient still. Patient opened eyes and looked round in a dazed way before leaving theatre. Continuous oxygen and rectal saline given (routine) on return to ward. 5 p.m., unconscious, pulse 140, irregular, cardiazol and digitaline given. 8.30 p.m., breathing shallow; pulse 160, irregular. Lobeline, CO_2 and O_2 given, also digitaline, with very little effect. Pulse and respiration became feebler and feebler and patient died at 9.45 p.m. No post-mortem examination.

The Barbiturates

There are many barbituric acid compounds in use and they vary greatly in toxicity. Two facts which are important with regard to the effects produced by the barbiturates are: (1) The more toxic the compound, the smaller the dose required to produce a hypnotic effect; and the more rapidly is that effect produced. (2) The smaller the dose, the shorter the period during which the drug will act; and the more rapid will be its elimination from the patient's system.

The barbiturates have been used in various forms for many years; they are essentially hypnotic drugs and only produce anaesthesia in large and dangerous doses. Used as basal hypnotics the optimum dose is comparatively easy to judge, especially when given intravenously; but it is a different matter if the deeper stages approximating to anaesthesia are intended; it is very easy to administer an overdose. Morphine given beforehand increases their action, and smaller doses are needed to produce unconsciousness. As a general rule the systolic blood pressure is lowered some 20 to 30 points after the intravenous administration of a barbiturate, slightly more than this if morphine has been given. In many of my cases the blood pressure returned to normal within about ten minutes. It can always be raised by the inhalation of a little ether.

The hypnotic state resulting from the administration of a barbiturate has been divided into three stages. These merge one into another, and in the transition either into, or out of, complete unconsciousness a patient may pass through each stage; but absorption or elimination may be so rapid that the stages are indistinguishable. These stages are:—

1. Complete unconsciousness. Only obtained when a dose sufficiently large to be effective has been administered. The corneal reflex is sluggish or lost, but unless considerably more than a hypnotic dose has been administered, the patient will respond to painful stimuli.

2. A stage of semi-consciousness, during which a patient can be roused, will take drinks, and speak, but will lapse into sleep again when left alone. Some few cases (especially children) become restless in this stage; this may vary from slight movement to great excitement requiring forcible restraint. The patient has no memory whatever of events which have taken place during this period.

3. A period during which the patient is quite conscious, but feels drowsy and will sleep if left alone.

Elimination of Barbiturates

I am unable to learn anything very definite about the elimination of the barbiturates. Probably they are excreted by the kidneys, after having been broken up by the liver. I gave 4½ grains of nembutal by mouth to a patient who was suffering from toxic jaundice. He fell asleep immediately, and we were able to extract several teeth without an anaesthetic. He remained unconscious for 10 hours and drowsy for two days. The probable explanation of this appears to be that his liver was unable to deal with the drug.

An antidote has been stated to be caffeine sodium benzoate. I administered this to a woman who had taken a large amount of dial. She was deeply unconscious, with no corneal or other reflexes. I gave her caffeine 0.5 grm. with sod. benzoate 0.5 grm. intravenously, and although she did not regain consciousness immediately, her corneal reflex returned, and she moved when pricked with a needle immediately afterwards. Thyroxine, by raising the metabolic rate, is also said to hasten elimination. Zerfas reports that animals given fatal doses of sodium amytal died of respiratory failure which usually precedes that of the circulatory system, though failure of both sometimes occurs simultaneously—particularly if the drug is injected rapidly.[1]

Administration of Barbiturates for Basal Narcosis

The three barbituric compounds which have lately been employed as basal narcotics are:—sodium amytal (sodium iso-amyl-ethyl-barbiturate); nembutal (sodium ethyl—(1 methyl-butyl)—barbiturate); and pernocton (sodium salt of secondary butyl-β-brom allyl barbituric acid). They are all quickly acting drugs and very toxic, but nembutal and pernocton are twice as toxic, and therefore twice as powerful, as sodium amytal. The latter must be administered in larger doses and the recovery period is therefore longer. Nembutal and pernocton are said to be equal in toxicity, and I think that is borne out by their recovery periods, which are approximately equal.

Pernocton is supplied ready for injection in 10 per cent. solution which saves time, but in my experience it is neither so easy to use nor so pleasant for the patient as nembutal. I have only given it intravenously and the small bulk makes the dose difficult to judge—several of the cases vomited during both administration and recovery periods, and in several, excitement was present during both periods. With nembutal, I have seen practically no ill effects, apart from occasional cases of excitement during recovery. This occurs in a small proportion of adults and is seldom extreme, but it is much commoner with children, especially when administered by mouth.

Whenever possible it is preferable to give the barbiturates intravenously. They may, however, be administered intramuscularly, or by the mouth or rectum. By these routes their action is delayed and the correct dose is more difficult to judge. Intravenous administration is easy and the minimal effective dose—just enough to produce unconsciousness, and no more—which is desirable, can be gauged with accuracy.

Amytal powder is supplied in 1.0 grm quantities and nembutal in 0.5 grm. quantities, sterilized in ampoules. Immediately before use solutions are prepared by dissolving the powder in 10 c.c. of sterilized distilled water. Amytal is therefore administered in 10 per cent. and nembutal in 5 per cent. solution. Pernocton, which is

[1] *British Medical Journal*, November 29th, 1930, p. 867.

more stable, is supplied in 10 per cent. solution in ampoules containing 5 c.c. The solution is run into the vein very slowly (1 c.c. per minute); meanwhile the patient is engaged in conversation. As the injection proceeds his speech becomes more and more slurred, until finally he fails to answer questions, and sinks into a deep sleep. The administration is stopped immediately he loses consciousness. In this way correct dosage is ensured.

If a small dose of morphine and hyoscine be given beforehand, the intravenous injection is often not remembered at all. Usually very little anaesthetic is needed, although patients vary considerably in this respect; but even after ether, vomiting is practically unknown. Recovery, as a rule, takes place in from two to six hours, followed by the protracted period of drowsiness already mentioned, which may last as long as twenty-four hours.

Illustrative Case

Man aged 56.—Operation: Partial gastrectomy. Heart and lungs, nil abnormal. Blood pressure, 140/80. Fit man of 11 st. 5 lb. 9 a.m., hyoscine compound "A" (hyoscine hydrobrom. gr. $\frac{1}{100}$, morphine sulph. gr. $\frac{1}{6}$, atropine sulph. gr. $\frac{1}{150}$). 9.50 a.m., nembutal 7 c.c. of 5 per cent. solution in sterile distilled water intravenously. Patient went to sleep in midst of a sentence. No excitement. 10 a.m., anaesthetic, nitrous oxide and oxygen with very little ether; good relaxation very easily obtained. Blood pressure, 115/60. 11.25 a.m., returned to bed. Blood pressure, 110/60. Good colour, breathing normally. 2.15 p.m., recovered consciousness. Pulse good. Slept until 4 p.m. without morphine. Final recovery uneventful.

I have no deaths or mishaps to record with the barbiturates. The only case in which they were blamed (I feel sure unjustly) for subsequent events was this:

A girl of 16, apparently healthy, but with a history that she had had several faints and that her fingers often went blue, had an operation for appendicitis. She was given atropine gr. $\frac{1}{100}$ and 5 c.c. of a 5 per cent. solution of nembutal intravenously before operation. No morphine. The anaesthetic was open ether. The operation period was normal and uneventful. While the dressings were being applied, and some minutes after the ether administration had ceased, she quite suddenly stopped breathing and her pulse became impalpable. It was only after the most energetic restorative measures that she started to breathe and her pulse returned. Subsequently she had about forty convulsive fits, probably the result of failure of her cerebral circulation. She did not regain full consciousness for two days, but she finally recovered completely.

I have no idea what caused this patient's collapse—her pulse was good and she behaved in a perfectly normal manner before and during the operation; but I feel sure that, whatever the cause, it cannot be justly attributed to the nembutal she had had.

Conclusions

I must confess a personal preference for either paraldehyde or nembutal. For children I like the former because the barbiturates must generally be given to them by mouth or rectum, and thus administered they so often cause restlessness. For adults nembutal gives equally good results and is less worrying to the patient than paraldehyde. Post-operative restlessness when present is usually slight and may be controlled by morphine or rectal paraldehyde. I think that both paraldehyde and nembutal are eminently safe in expert hands.

Combinations of drugs act more powerfully, and smaller doses are needed than of any one drug alone. Elimination is easier and quicker than saturation with one. A little morphine, just sufficient nembutal or paraldehyde to produce sleep, and then nitrous oxide and oxygen or ethylene, with a minimum of ether if necessary to produce relaxation give the patient most protection, least injury, and easy awakening.

Intravenous narcosis marks a distinct advance in the administration of anaesthetics. The advantages of minimized risk are sufficiently great in themselves to warrant its use; but since, in addition, it enables us to ensure for our patients absence of vomiting and a post-operative period of unconsciousness, during which most of the anaesthetic is eliminated, and a great deal of pain evaded, its use is doubly justified. The public are beginning to recognize its merits, and I feel sure that before long the demand for it will be general.

A certain amount of experience is necessary before one can hope to obtain consistently good results. The administration of an anaesthetic becomes a very different procedure from the older methods we have been accustomed to; and it will be regrettable if reproach is brought upon basal narcosis by the inexpert.

CONGENITAL TALIPES EQUINO-VARUS*

BY

DENIS BROWNE, F.R.C.S.

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

A case of talipes equino-varus is almost invariably introduced by its mother to the surgeon in the same words: "the baby's feet are twisted in." Too often the only result of long treatment is a change of phrase, much the same appearance coming to be described as "persistent inversion." I propose in this lecture to take the mother's remark as a text, to examine what the "twisting in" actually means, to argue that it is the main element in the deformity, and finally to describe a splint specially designed to combat it.

The Nature of the Deformity

It is, of course, almost impossible to add anything to the many minute descriptions of the anatomy of talipes. My purpose is rather to try to simplify our ideas of it, for if every departure from the normal of every constituent of the foot is separately described, it is beyond the powers of most of us to fuse these elements into a coherent mental image. I think the best way in which to do this (though I am far from wishing to reopen the sterile controversy over the causation of the condition) is to say that the deformity is exactly what would result had the plastic feet of the foetus undergone long-continued pressure, while pinioned in a cross-legged position against the concave constricting walls of the uterus. If anyone wishes to see what this purely hypothetical position may be, he should procure a newly born specimen of talipes and suspend it in a landing net. The manner in which the "butt-end" folds up into an ovoid shape and thereby accentuates the deformity is very striking (Fig. 1).

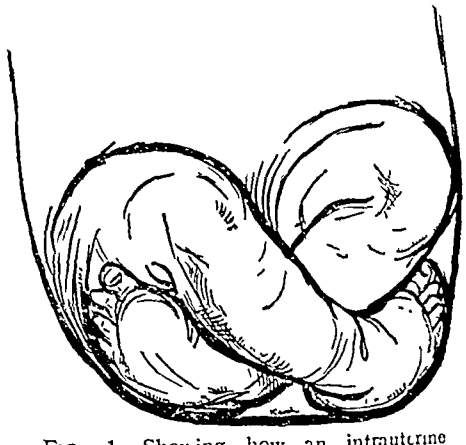

Fig. 1.—Showing how an intrauterine pinioning of the feet could produce the typical talipes deformity.

* A lecture delivered to the post-graduate class at the Hospital for Sick Children, Great Ormond Street.

The effect of pressure of this sort is confined to the foot, the tibia being prevented from bending by the support of the opposite limb against which it is folded, and prevented from rotating by the balance of the pressure on the heel against that on the toes. The foot itself is moulded so that its outer surface conforms to the curve of the inner surface of the uterus, which means that it must be curved longitudinally throughout its entire length. This length is divided into a long anterior part (the fore-foot or foot proper) and a short posterior part (the heel) by the fixed point of the ankle-joint. The argument of this lecture is *that this longitudinal curve of the fore-part of the foot is the fundamental part of the deformity, that "twisting-in" which is the first thing that strikes the lay observer, and the last thing that defies the surgeon.* It is neither the equinus nor the varus of the classic name; they are merely secondary to it, and are its inevitable consequences. No degree of pure equinus nor of varus will produce this longitudinal curve, but it is impossible to bend the fore-foot inwards in this way without swinging the foot as a whole into equino-varus. The proof of this (and of the extremely important converse theorem that bending the foot outwards swings it automatically into calcaneo-valgus) I prefer to leave to a short experiment rather than to a long dissertation on the axes of joints (Fig. 2).

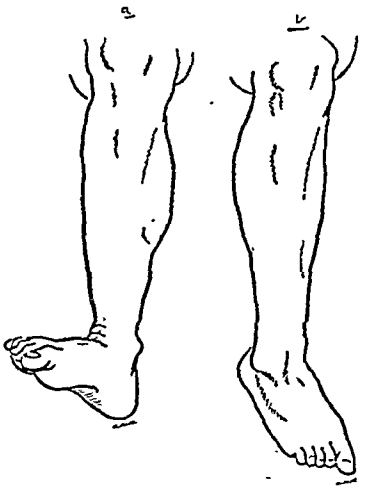

FIG. 2.—*a*, Showing how the foot, when twisted outwards, either actively or passively, to its limit of movement, goes into calcaneo-valgus. *b*, Showing how, on being forced inwards, it goes into equino-varus

To sum up, the deformity can be resolved into three elements in three planes at right angles to each other: the equinus, best seen from the side; the varus, best seen from the front; and the longitudinal curve of the entire foot, best seen from the rather unfamiliar aspect of Fig. 3, which masks both the other elements. In my opinion this is by far the most instructive view of the condition at any stage. A child lying in this position with free legs shows both the longitudinal curve of the foot itself and the relation of this deformity to the rest of the body. The position usually chosen to illustrate progress, erect on a carefully arranged foot, is only too apt to deceive the surgeon as well as others.

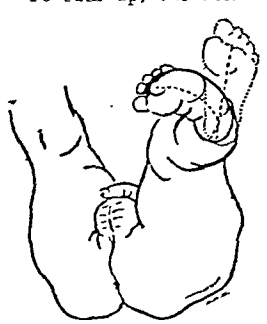

FIG. 3.—View of talipes of left foot to show longitudinal bending. The shape and position of a normal foot are shown in dotted lines.

So far the deformity has only been considered structurally, but functionally also the curve of the fore-foot is of primary importance. Experiment again will prove that if the normal foot is walked upon when turned inwards it goes into a talipes-like position, with a weight-bearing outer border and a contracted and lifted inner one. Conversely, the effect of walking upon the foot when turned outward into the "Chaplin" position is to bring the weight on to its inner border and so stretch and flatten it.

Consequently, whatever measures may be taken to correct the deformity, if they leave the child walking with the fore-foot pointing inwards, a vicious circle is set up. The mal-alignment of the foot increases the deformity, and the deformity increases the mal-alignment of the foot. This action accounts for the familiar rapid relapses of feet which, when suitably posed, appear almost perfect. It must be impressed on all concerned that if the feet are used pointing outwards they will improve, but that if they are used pointing inwards they will get worse.

Principles of Treatment
